I'm certainly not collecting Motorola DSP type transceivers. This is
the noisiest newsreflector I've ever tried, and when most of the posts
are concerned about recent equipment it seems better to unsubscribe
ASAP and leave the reflector for the appliance operators needing info
for complex solidstate blackboxes

--> Funny story related to this: I was working on a Drake TR-4. I'd just taken the bottom cover off and reconnected the power supply to do some voltage checks. Switched on the power and got a loud "CLANG!!!" Startled the heck out of me! Once my heart rate had gone back down, I realized I'd left the cover lying loose on top of the supply, and the strong magnetic field created by the hefty inrush current had vibrated it.

Chris,
I wouldn't worry about the 18v, which may seem high
to you. Remember, this is a nonregulated power supply,
the 'idle' voltage will be higher than 'normal'. The
voltage under load will be down around 13 volts give or
take a fraction or two. Normal behavior for Icom power
supplies.

Buyer to pay S/H.

Send all inquires to: servis_za_elektroniku@iname.com

3196. Re: Howto kill Transformer Noise ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-19 00:00:00 UTC
From: "John C. Ko" <n2fno@att.net>
Message-ID: <NEgL4.12661$PV.867280@bgtnsc06-news.ops.worldnet.att.net>
Source record: 61301

What I have found out are ;

1) The transformer was NOT treated with any kind of enamel or etc...
2) 4 bolts hold transformer core together was not tightened enough.
3) There were no way to tighten the front panel to top cover. When
transformer vibrates, the front panel amplifies its signal.

I finally made to attenuate 60Hz HiFi audio at least 60 db after 30 min.
labor.

1) tightened the 4 bolts (do not over tight !, they used cheap bolts and
nuts.)
2) Drill out rivets and replace them with rubber washer (radio shack
parts), bolts and nuts.
3) fill the front panel gap with weather sponge tapes (HomeDepot parts).

I thank you again for all great ideas posted here.

Regards,

John / N2FNO

I appreciate the reply -- I called Icom about a week ago to obtain information and the tech mentioned a case of someone damaging their Yaesu rig using this power supply. He also mentioned the rig designed for this supply (IC-701) performed the voltage regulation for 13.8 volts. Should I still be concerned when using this supply with the mirage amp? By the way, I measured the idle voltage at 17.4 volts.

Singer products were acquired by Eaton Corp about 20 some years ago. Actually I believe another company bought Singer first then Eaton acquired that company. Eaton is a huge company which owns many many companies. Some of the Singer products I believe ar still manufactured. You may have to dig on there site to find the right division.

Chris,
I really don't think it would hurt to use this power
supply with any radio/amp/etc as long as the supply's
current rating isn't exceeded, or approached too closely.
You shouldn't have any problem.
'Doc

Well, I wouldn't risk it. The difference between 18 V and 13.8 V
is enough that it's possible that something in the radio will be
damaged by 18 V even though it's probably designed to handle 15 V
(13.8 plus some safety margin) forever.

Thanks Fellows, but stripping #30 and #28 stranded is sure more difficult
than say #26, #24 stranded and larger? And the other thing I notice is for
the stiffness of the insulation after soldering #30 or #28 onto the
terminal, any lateral movement without a strain relief will shear the
connection pronto if there is the slightest nick on the wire?
So far, crushing the insulation, nicking it from behind, then pulling, seems
to work the best with the small stuff. Larger wire is simply no problem, in
pulling the teflon off with the Miller stripper as Brad mentioned. I think
that I will stay away from the heat method for the lack of ventilation?

This doesn't meet your requirements, being thinner and narrower, but if you get desperate, you can find Teflon tape at any store that sells plumbing supplies. It's used to seal pipe threads. Does a good job, too.

I don't see those problems when I strip #30 stranded TFE. I usually
use the hand stripper with a row of sized cutting holes. I gently
close the stripper to cut the insulation, and then IMMEDIATELY OPEN IT
UP SLIGHTLY, to GENTLY push the cut insulation tube off the wire. One
could probably pull it off by hand just as well. I do not see strands
breaking when I make connections. But I do make sure the solder flows
back into the insulation slightly, thus strengthening that area.

>So far, crushing the insulation, nicking it from behind, then pulling, seems

The one I've seen recently seems to take a while to heat up.

This is a radio agc/squelch amplifier from National.
Its in there Linear Data book from 1976.

Perhaps you can search the WEB for LM170 or LM270.
Its the same circuit but diff. temps.

Plumbing supplies have teflon tape used for thread sealing- in different
widths. However, the thickness is probably only 0.5 mils.

I have a copy of Stutzman and Thiele, but it must be a
different
edition. I find the formula for A_em on page 59 (chap 1
section 10).

Page 172 is the problem section at the end of chap 3
(arrays).
I cannot find that table. Could you give the chapter,
chapter
title and section (hoping that they at least used the same
organization)?

Opinions expressed herein are my own and may not represent those of my employer.

FWIW, you can get "standard" and "heavy duty" pipe thread sealing tape. I'd look for the "heavy duty" type. The stuff I have is pale orange, vs the white for the standard. You might be able to do a spiral wrap with significant overlap to build up the thickness, if the tape is too thin.

I've also picked up some surplus Teflon tape, ticker and with adhesive coating, at Boeing Surplus...but dunno where you'd find it at a reasonable price new.

Cheers,
Tom

Have a look at back issues of "Electronics World + Wireless World"
magazine out of the UK. They've had some wonderful articles on early
radio technology over the years. For example, they described in one
article some high-powered spark transmitters (spark, not Poulsen arc
or alternator) running in excess of 100,000 watts. (Noooo---please do
NOT try to do that with your demo!)

Cheers,
Tom

3224. Your favorite FET?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-20 00:00:00 UTC
From: "Ralph E. Carter" <carterr@bellsouth.net>
Message-ID: <38FF718C.296426AA@bellsouth.net>
Source record: 61329

What is your favorite small-signal, low-noise FET
for 3-30MHz?
Not being an expert, and studying the tech sheets,
and looking at applications on the internet and in
the ARRL Handbooks, here is what I've found:

MPF102 This is inexpensive, and would probably work
fine anywhere in an HF preamp or receiver.
Its published tolerances are wide, though.
Its gfs is very low.

J310 This looks super-primo to me. If the tech data
can be believed. The cost is still OK, but there
are fewer sources. Gfs is high. Using these in
the first stage, with grounded gate, seems popular.
Why? (U310 is in a metal can.) There is a graph
of its intermod performance in the tech data I have.
It is drastically better than the similar graphs
in the files for other JFETs I've seen (I can't
remember which.) This suggests that it could tolerate
large signals and would be easier to use in that
first preamp stage.
When I've run models of this in SPICE, its gain has
tended to be low. I think lower gain with greater
dynamic range would be easier to work with.

40673 This is an extremely good dual gate mosfet that
NTE222 would be fun to play with. It cost ten times
as much. If one needed this function, couldn't it
be done almost as well with totem-poled JFETs?

2N4416 I see this is very popular. I don't know why.

2N5484 These aren't mentioned as often. I don't know why.
2N5485 The specs look very good to me.
2N5486
2N5670
2N5668
2N5669

Studying this issue is difficult, because I'm not sure which
specs to favor.
Any of these would work very well. I like the J310 best.
Charles Kitchin, N1TEV, seems to know what he's doing. In his
circuits I've seen, he has used 2N4416, J310, MPF102, and the
BJT 2N2222, all in similar applications (preamps and simple

receivers). These four devices are quite different.

3225. Toroid core mix- what I found.

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-20 00:00:00 UTC
From: "Ralph E. Carter" <carterr@bellsouth.net>
Message-ID: <38FF775D.A5D70A9F@bellsouth.net>
Source record: 61330

I have the Amidon tech booklet.
This is interesting, and there are many
variables to consider.

10 MHz:
(This is the geometric mean of the HF band.)
Fixing the frequency at 10 MHz, the inductance
between .2uH and 1.8uH, wire size as big as
will fit on the core, and studying the Q-curves
provided in the booklet, extrapolating a little
where necessary, I found:
The bigger the core, the better, limit unknown.
For any size core, -6 was better than -2.

5 MHz:
For this frequency, I looked at inductances between
.4uH and 3.6uH.
Results:
For core sizes <= T-50, -2 was slightly better.
For core sizes >= T-68, -6 was still better.

I am interested in receiving, around 4.7Mhz to 22Mhz.
Unless I learn something else, I'll probably use
> T-68-6 wherever powdered iron is called for.
(Possible exception: when filtering out the BC band.)
I like handling larger parts and heavier wire anyway.

3227. Braiding small wires.

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-20 00:00:00 UTC
From: "Ralph E. Carter" <carterr@bellsouth.net>
Message-ID: <38FF7C4A.4FC1A2F@bellsouth.net>
Source record: 61332

This is about winding typical inductors for HF.

Reducing HF resistance by choosing very large
wire diameters, after a point, leaves a lot of
wasted copper and space, inside the wire.
At some point, using many smaller wires in parallel
becomes much better.
The governing equations are somewhere on the internet
and elsewhere, so one could strike a balance.

One thing I haven't seen, is how to braid Litz wire.
Can someone point me to this?

I think laying the wires in parallel, or twisting,
or ordinary braiding, would work OK.

I have some old texts I can't get to right now, that
describe this, and basket-winding, and pye-winding,
and all of that other neat stuff. I haven't decided
whether or not to wind my RF chokes too. I can't study
everything at once.

Source record: 61334

I prefer the 2N4416 over the MPF102. The problem with the MPF102 is its extremely wide specification range. So you can't predict within any reasonable bound what the Idss or zero-bias Gm will be, for example. The 2N4416 has essentially the same specs, just with more reasonable limits. The MPF102 would be ok in some applications, and ok in others if you're willing to select one, have a bucket of them to select from, and don't want to make many copies of the circuit or have anybody else duplicate it. But I find it hard to apply to a lot of applications because of the wide specs.

Circuit #1:
Antenna goes through 100pF and then sees two things-
a 200ohm resistor to ground, and the source of the
grounded gate Q1, a 2N4416.
This source offers a low impedence.
A 75 ohm antenna input is specified.
I understand this.

Circuit #2:
This circuit is by the same author.
Antenna goes through 50pF and then sees two things-
a 200Kohm resistor to ground, and the gate of the
grounded source Q1, a 2N4416.
This gate presents a high impedence.
The antenna impedence is not specified.
This high impedence would make it less necessary to tune
out the reactance of an untuned antenna, and this would
make it easier to use with random antennas. Yes?
(The circuit was intended "for beginners".)
But otherwise, I don't understand how this can be
close to right. That input should be somewhere between
50 and 600 ohms or so. Right?

(These interesting parts of these circuits were elsewhere,
thus, these inputs were not necessarily intended to be
optimized. But for top performance, shouldn't there be
only reactances, where those resistances are?)

Hi.
I've appreciated many of your postings, and I've saved some of them.
I think I saved your last big posting on "skin effect".
I started studying Spanish.
Then I started to listen to Spanish on shortwave.
Then I started wanting my radio to work better.
So now I'm playing with circuits again, instead of studying Spanish!
Bye.

Yes, I agonized over these issues at audio frequency, in the past, and I
can't go through that again! I think I'll be an expert on something
else, and just buy these! Thanks.

The 40673 is no longer made and nearly impossible to find. Since I also use VHF the J310 is my choice and works well in whatever I've used it for. In a common gate configuration it's gain is about 10 db and very stable. In common source gain is of course higher but still works predictivly well. Works for me but opinions may vary.

> Can someone point me to this?

Well, the Litz I've seen in loading coils and variometers in the transmitters I used---wires up to 1/4" diameter---were not braided or woven. They more closely conformed to ordinary rope manufacturer; in other words, a number of fibers are twisted together to form yarns, which are then twisted together in the opposite direction to the fibers to form strands. The strands are twisted in the opposite direction to the yarns to form the completed rope. Though in the case of Litz wire yarns were twisted to form strands whereupon they formed the actual wire---the basic wire (#40 or so) are the yarns so to speak and formed strands of 40 wires each perhaps, thence a number of strands twisted into the final Litz wire whereupon it is finished with two spiral wraps (in opposite directions) of what seems like cotton fibers.

I reckon if a fellow wishes to make their own Litz wire it could be a nice home project---certaintly not outside the capabilities of the advanced home shop machinist.

I really like the Philips BF904. It has a special biasing circuit
that makes it much easier to get consistent bias current. It is a
dual gate MOSFET with 30 mS transconductance and less than .1 pF
feedback capacitance. They are intended for UHF TV tuners. NF
is about .5 dB at 100 MHz.

Very interesting.
The Philips guide says "VHF/UHF".
These are in the tiny surface-mount packages.
They are about $.21 each, in very large quantities.

There has been an article/report in EE+WW recently (past 2 yrs)
about trials to replicate spark Tx using an auto ignition coil. I don't remember
the exact date but I do remember it was tested in an abandoned railroad
tunnel. Failing that The Admiralty Handbooks of Wireless Telegraphy are a
mine of information about spark Tx & associated Rx (my copies 1925 &
1938). Did see copies of both Vol 1 & 2 while browsing a Bellingham WA
2nd hand bookshop & wondered how they got there. The earlier edition
(1925) is probably better as the 1938 is already describing the spark Tx as
obsolete, if you can only find a later 2 vol. set you'll need Vol 2.
Another source of info see High Power Wireless Equipment (Articles
from Practical Electricity 1910-11) reprinted by Lindsay Publications Inc.,
Bradley IL 60915 (ISBN 0-917914-95-3), this'll even tell you how to enamel
the Cu wire you're going to need to make that 2kW spark gap Txfmr.
For info on coherers & detectors Early Radio Wave Detectors by VJ
Phillips is excellent, (ISBN 0-906048-24-9) as Vol 2 of the History of
Technology Series. Publ. Peter Peregrinus Ltd (in association with The
Science Museum, London). Connecting a frogs leg to a pointer moving
across the smoked surface of a moving drum and wiring your Rxd signal to
the frogs sciatic nerve (operating time limited by onset of rigor mortis) is nearly
as original as signal detection by taste - 2 small silver contacts placed in the
mouth, 'a slight difference in taste sensation produced between 500Hz &
250Hz spark transmissions being reported (as well as a tendency to produce
a sensation of toothache in the front teeth !!!!)' but it's probably as well that
they didn't catch on.

From: Rick Haub <rhaub@midwestmicro-tek.com>
Message-ID: <3900A27A.F1430A42@midwestmicro-tek.com>
Source record: 61258

I found a great, simple QRP schematic on a web site. It's supposed to output about 5 watts and used a 7400 as the driver into the final transistor. Unfortunately the notes only say that "any rf transistor will do". I'm pretty new to hamming and I don't know what would be a good choice. The author of the web site has no e-mail link so I can't ask him. I get a lot of my stuff from (silver mica caps and tubes) hppt://alltronics.com , they have a lot of transitors and I'm sure at least one of them will do. Any suggestions?

Thanks,

Rick KC0GIX

All this talk about jfets has reminded me of a question that has troubled my mind from time to time.

Has anyone ever mounted the metal-case U310 by drilling a hole in a pc board and soldering the can in place? I'm guessing the jfet inside might not survive the operation, but if it did this would be a nice mechanically sturdy way of mounting the jobbies. Or maybe silver-bearing epoxy?

best regards,
ncc kb1dej

PS anyone know the origin of the term "cascode"?

yes ...

> I'm guessing the jfet inside might not survive the
> operation,

generaly they don't unless you are very fast or just solder the tab

> but if it did this would be a nice mechanically sturdy way of
> mounting the jobbies.

hot melt glue also works

> Or maybe silver-bearing epoxy?

The stuff absorbs water from the air. Then it tends to degrade. H10 is
especialy prone to this.

QST ran an article in the '70s on replacing the front end mixer circuit with a different one. As I recall, schematics for portions of the unit were in the article. Check the ARRL Web site which includes indexes of all their QST issues.

Having owned two PowerMites, I wish you the best with them - they were fun little rigs!

re: http://www.geocities.com/ck722transistor/
I was looking at this site the other day following a previous
post of yours.
How do you expect the search engine to find and catalog this web
site with each and every page totally graphical (that is: textless)
and with no informative meta-tags?

It is a Very Good presentation, tho'.

Dick's posting reminds me...long ago I had a book titled "The Boy Electrician." It had a wealth of interesting projects in it of the sort that boys--and others--tinkered with in the early 1900's, but somewhere along the way, I lost it. Darn. However, in searching some used-book web sites, I discovered that it has apparently been reprinted, and you can probably find a copy at a reasonable price. It would be a nice addition to a "spark museum" I think, even if you don't manage an original edition.

Cheers,
Tom

3264. Looking for Yaesu Programming Cable Or Schematic

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-21 00:00:00 UTC
From: Scott Bailey <sbailey@upgradebase.com>
Message-ID: <XB6M4.5966$pJ2.808144@news.pacbell.net>
Source record: 61270
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew,rec.radio.swap

I'm looking for the schematic or a cable to buy for for programming older Yaesu radios. I have a FTH-7008, although I believe the same part works for the following models:
FTH-2070
FTH-2008
FTH-7008
FTH-7009
FTH-2009
FTH-2011
FTH-7011
The cable I'm looking for plugs into the serial port and attaches to the microphone plug of the radio.
This is not the same cable as used for the newer VX series. That has a 4 conductor plug.

Any help would be appreciated.

I saw a spark xmitter on sale at e-bay a while back,probably not
there anymore but I have seen spark related equipment there on
quite a few occasions.
Also, look on ebay for early twenties and thirties books about
electricity or radio. I have a book titled "Principles of Radio
Communication" by J.H.Morecroft that contains a wealth of info
about spark gap telegraphy. copyright 1921. No isbn number
though.I purchased this book for 4.00 locally but have seen it
on ebay for less up to about 10.00

I have a new-old-stock TCS-14 transmitter for auction on eBay.

The URL is

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=314106127

and the blurb is

This is an unused and unmodified new-old-stock mint-condition example of the venerable TCS-14 AM/CW transmitter. Found as-new in-the-box, never put into military service, with no holes gouged out for coax connectors, no manky power cables grafted into the case, no mouse nests in the wiring, or any other defect usually found with these rigs. Covers 1.5-12 mHz, AM or CW, and with the appropriate power supply (not included), I believe it puts out around 35 watts AM, 50 watts CW. The inside gleams like the day it was produced, the panel and chassis have no corrosion or discoloration. Includes cabinet and shock mount feet as shown. Some of the packing material is stuck on the large front handle, but that will be easy to remove. I may clean that and repost a picture so I can see this fine old rig in all it's glory before it goes out the door. Unless you have a time machine, you're never going to find a cleaner example of a TCS transmitter -- don't pass it up !

Closes 4/30/00

Thank you.

Sent via Deja.com http://www.deja.com/
Before you buy.

With a 7400 for a driver I think he's going to have a devil of a time
getting 5 watts, at least in one stage. Plus he's going to need a ton of
filtering at that power. Better to go for a watt or so where some simple
filtering will result in tolerable harmonics.

Check the library at your local university. At my old school we have the entire collection of Popular Electronics in bound volumes---besides many other electronic hobbyist magazines (including QST). Most likely you'll find PE in a microform of some sort. Practically all schools have their card catalogs on the internet so check their holdings by going to the school's web site then to the library. Hey, I've even found the complete collection of Electronics Illustrated---although at another school a good drive from here.

As an alumni member of our library I've spent many hours re-reading Carl and Jerry. I have to admit, there was quite a bit of sarcasm in those stories that I never caught when I read them in my younger day.

I've started to copy those articles with hopes of printing the complete collection---I'm sure there are many out there that would like to re-read them

Yes, I have to admit, radio was wonderful back then... gosh how those old QST choke me up...

That's correct. It's recommended for 1-1/5 inch dia and larger pipe threads.

The very thin white stuff mic'd out at 2 mils. The pink tape mic'd out at 3 mils and the yellow tape mic'd out at 4.5 mils. The pink tape is labeled 1/2"x260" mil spec T27730! and cost $2.50 a roll. UL approved and made in China. All are 1/2 inch wide. I do not know how much tape is on the roll. I didn't unroll it to measure it! Hi. I suspect that the 260 refers to 260 inches.

Technical libraries I've visited have a microfilm viewer which has a
built-in printer -- press a button and you get a hard copy. If your
library doesn't have one of these, they've surely got some other means
to do it.

Hi Rick,
I believe Radio Shack is currently carrying the 2N3553, which would make a good HF QRP output transistor, with a heat sink on it. Another good one is the 2N5109. Any one you choose must have a heat sink if you want to try for 5 watts output. A 2N3866 would also probably work, but it is not so stable as the first two. I don't know what Alltronics is offering for transistors.

Yes, I was the one posting that info - National Semiconductor is obsoleting the LM3900. I know that part is second-sourced by TI, Motorola, and RCA, so we may not be totally out of luck, but I wouldn't use that part in a new design.

Message-ID: <sg3g4gfjl6e132@corp.supernews.com>
Source record: 61286

Hello Group,
I've finally put up my tower, (told the wife it was easier to mow around in the vertical position instead of laying down in the lawn). I put up four runs of hard-line up to various antennas, all in the 2 meters / 440 range.
I need some questions answered about antenna switchers.
1. Can I build one cheaper than buying one? (depends on what's in my junk box maybe?)
2. Are antenna switchers rated for HF or VHF/UHF?
3. I have a old Heath kit remote antenna switcher that mounts on top of the tower. It seems to me that the signal runs through the different relays that switch to the different antenna. Doesn't that effect the signal with a huge impedance bump on the higher frequencies?
I would be interested in a source of plans or circuit to build this little project.
Thanks for letting me pick your brains.

Hi..

I used to have lots of schematics for those things.. but I have no idea where to find them any more.. HOWEVER the modern versions are much more useable and easily subbed in the devices.. in fact all the new signal transsistors are more freq responsive and wider ranged than the old sb-100...

Yes, I love the old cheap homebrew stuff.. QRP and AM and CW only and hey, some of those superregen recievers were more selctive than my more modern midland...

A good source of RF power transistors is junk CB radios. The driver and final amp make good QRP transmitters. The final amp is usually rated for pretty good voltage since AM operating voltages are higher than CW or FM at the same DC power input. In other words, they can stand more abuse. You can usually get over 5 watts out.

Many CB radios are thrown away or given away for free...I have salvaged many good parts from them, including the synthesizer chip, which was also used in an number of ham rigs.

Don Lancaster, his website is http://www.tinaja.com mentioned John T. Frye
a few months back in one of the sci.electronics.* newsgroups in a thread
about the hobby electronic magazines (there have been a few in recent months.
Unless he was confusing Frye with someone else, he seemed to have some
insider information that he only hinted at; Don of course was a
regular contributor to Popular Electronics 35 or so years ago.

I was under the impression the Carl and Jerry stories ended because
the magazine went through one of it's periodical morphings. In the
early/mid seventies, John T. Frye had a column/series in Popular electronics
about electronic repair. It was similar in fashion to the Carl & Jerry
stories, in that he had a fictional story to do some teaching. It was
based in Mac's repair shop, and had a grizzled old tech, and a young
and fresh out of school assistant, and their receptionist.

I'm not sure when it started, or how long it ran for. At the end
of '71, Electronic World was merged into Popular Electronics, and
I lost interest for a while. I'm under the impression that John T.
Frye might have been writing regularly for Electronic World (which
was published by the same company as PE) after the Carl & Jerry
stories ended.

I don't follow copyright laws, but the I know they used to be more
limited than nowadays. The stories were published 35 to 40 years ago,
and that might put them into a copyable position now or soon.

To confuse the issue further. The Popular Electronics that ran
the Carl & Jerry stories shutdown in 1983 or '84, having followed
the computer boom it started with the Altair 8800 in January 1975.
The magazine morphed a couple of times, including changing it's

name to Computers and Electronics, and trying to focus more on computers; they seemed to be trying for the consumer market and they lost the existing readership without gaining new readers.

The Popular Electronics that was published until December 1999 was not the same magazine. Some time after PE died, Gernsback started a bi-monthly hobby electronic magazine, Hands-On Electronics. After a couple of years, it went monthly and they changed it's name to Popular Electronics, and maybe rearranged tiself a bit to resemble the PE of old. I vaguely recall the changeover, and I always assumed they had gotten the name some years after the original PE shut down. If I recall properly, there was an editorial where they talked about it, and the wording was such that it sounded like they had just gotten the name, some years after PE stopped being published.

So did Gernsback just get the name of the magazine, or did it buy the assets? That might have relevance where copyright is concerned.

And of course, Popular Electronics doesn't exist anymore, for the second time. Gernsback merged Popular Electronics II with Electronics Now (was Radio Electronics), and renamed the whole thing Poptronics, starting with the January 2000 issue.

It seems to be more PE than EN, and Don Lancaster mentioned about a month ago that they don't want his column anymore.

I admit that CB sets can be a good source of parts, and I've found them
both in the garbage or for five dollars or less at garage sales and hamfests.

But the last two CB sets I saw this way did not look like the final
transists would be in good shape. The circuit boards were partially
burned. And as I saw your post, I couldn't help but think that maybe
someone tried to boost the power, and burned something that way. It
strikes me that the final in a CB set may have already taken some
abuse.

Of course, what I'd really like to find in the garbage is an SSB CB
set.

3310. resistors to stop vhf parasitics?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-23 00:00:00 UTC
From: n2cqr@erols.com
Message-ID: <39032001.450303161@news.erols.com>
Source record: 61212

I was reading through some of the old W1FB articles in QRP Classics. At one point he discusses the use of low value resistors in HF circuits to suppress possible vhf oscillations/parasitics. How does this work? Is is because the resistors have some inductance that affets the vhf? Does this mean that ordinary old carbon resistors wouldn't work in this application?

Thanks, 73 Bill N2CQR

Thanks for the chronology of PE... it all comes back to me now... I guess that's why I liked Electronics Illustrated more that PE---it was so much less stuffy! Besides that, EI graphics were so much better and the projects were more enjoyable and accessible to mainstream builders---and not to forget UNCLE TOM'S CORNER! Odd that PE is remembered so well and EI has been seemingly forgotten although if the subject is brought up in informal meetings EI never fails to bring back fond memories.

It was nice to have have had a hand in the reprint (original wiring diagrams and pictorials) of a 1968 W5LET EI transmitter project some years back in CQ magazine---it was my attempt at bringing back to memory Electonics Illustrated magazine.

The resistor must be just NON-INDUCTIVE for this purpose. The resistor introduces some loss in the circuit in such a way that it damps the parasitics without jeopardizing the normal circuit gain. Carbon resistors are good for this sake.

In the magazine every month there was a story about two teenage boys. Not sure if the stories ended or not as I quit the zine about 25 years ago. They were in high school when I started reading around 1961 and had gotten to be freshmen in college about 15 years later..One story comes to mind where they went to buy a car and did things like using a microphone to listen to a bad wheel bearing. Another time a FBI agent needed them to erase a tape that a spy had. They built a device in a attache case out of a big coil of wire and a dc to ac converter and as they were getting on a train they rubbed that against the case the spy was carring. Their first week in college got them in trouble with the dean. They put a speaker in a mail box and ran some fine wires to the dorm room . They used it to talk to people. One was the dean of the college.

They did not use the electronics to get into trouble , but gave some ideas on what could be done with simple around the home devices in many cases. BTW they were also suspose to be ham operators.

Here's some additional info on the use of resistors. I'm still not
clear how this works:

DeMaw put a 10 ohm resistor near the collector of a class A amplifier
designed for operation at 7 MHz, explaining, "At 7 MHz the resistor
offers minor resistance to the signal, but at vhf it looks like a high
impedance, this prevents parasitics."

My question is, HOW does this work? Why is the resistor only a minor
resistance at 7 MHz but high impedace at vhf?

The traditional VHF parasitic suppression gizmo is/was about a 10 to 30 ohm resistor with three or four turns of number wire on the body of the resistor. At the normal operating frequency the resistor was shorted out by the coil. At VHF the coil looked like an open circuit and the resistor came in to play.

Even a small resistance in series with the output tank would de-Q it enough to drop the gain at VHF. Once you got rid of the gain you got rid of the parasitic oscillation.

These days you might see ferrite beads used to do more or less the same sort of thing.

I found the problem. I didn't realize the 16F84's had a security lock
on the program area. I wanted to make a backup chip for my controllers
before I put them in service, but I can't.

NHRC has posted the code for their first controller, but no other.
Sometime back I received a nice reply basically stating that they
wanted to provide the source to the Ham community, but someone started
using it for profit and they had to make it off limits.

So much for trying to be nice...

Bill,

This is a complicated subject but in a nutshell...

When we draw schematics of our circuits, we put in resistors, inductors, capacitors, et cetera as if they are "pure" components. A resistor is only a resistor, we don't account for its lead inductance and shunt capacitance, for instance.

At lower frequencies, this simplification is appropriate, however, as the frequency increases, the effects of these "stray" or "parasitic" paths become more important and must be acounted for.

Active devices too are impure, a bipolar transistor for example, has internal inductances and capacitances that affect the frequency response of the device. If these internal reactances were not a problem, we could have just a few types

of transistors; a big fat die that works as a series pass transistor in a power supply could be used at 1 GHz in a power amp for instance. Alas, the big die's internal capacitance prevents its use at higher frequency.

Again keeping it simple, let's look at an NPN transistor. At DC, if we increase the current into the base, there is a proportional (greater) increase in the collector current. These currents operate in lockstep, ie, they are exactly "in phase."

As the frequency of operation increases, however, the internal reactances start to modify this nice phase relationship. If we are not careful, at some point this internal phase shift in conjunction with some of the "impurities" of our external components causes instability. The worst case instability is oscillation at the "parasitic" frequency, however, difficult tuning, noisy operation, et cetera are also symptoms.

Note that in the above example, the "frequency of operation" may not be the desired frequency, but an undesired (usually higher) frequency.

Small value resistors placed very close to the device terminals help prevent instability because they modify the gain/phase relationship of the device at the parasitic frequency (ies). Compared to the external impedances of the tuned circuits, the resistors are small enough that they have little effect. Compared to the tiny internal device impedances they have a more pronounced effect.

So the partial answer to your question: "Why is the resistor only a minor resistance at 7 MHz but high impedace at vhf?", is that the resistor *value* is the same at all frequencies, but its *effect* is different at different frequencies.

Note that the selection of resistor values was often a "cut-n-try" or "black magic" process. Nowadays, with modern computing power and accurate device models,all of this stuff can be predicted and the design process is more "pure." Not necessarily more fun tho...

73,

Wes Stewart N7WS

You also might try and find a copy of H.M.Dowsett's excellent
"Handbook of Technical Instruction for Wireless Telegraphists".
My copy is the 4th Ed published, I think, in the early thirties by
Iliffe & Sons Ltd, London for "Wireless World".

In my experience we still used Marconi 1/4kw QG transmitters as
installed lifeboat equipment as late as the mid fifties, and it was
certainly an PMG exam item at the James Watt College in Greenock
around 1951.

Probably due to followup postings in rec.radio.amateur.equipment --
where CB'ers ask how to boost the power of their rigs and they'er
told to plug the power cable directly into 120VAC -- thereby
multiplying their power 10-fold in shifting from 12V. <g>

Don't forget, the gain of a transistor is inversely related to frequency.
That 20 ohms is going to mean a lot more where the gain is 2 than where it's
20.

3329. Re: resistors to stop vhf parasitics?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-23 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <8dvcoi$5m6$1@uranium.btinternet.com>
Source record: 61231

A low value resistor in series with the control grid of a tube, in conjunction with grid input capacitance, reduces gain at higher frequencies and ensures absence of VHF or UHF parasitic oscillations. Such oscillations use circuit inter-component wiring as 1/2-wavelength tuned circuits.

The resistors damp down possible resonances. Used mainly as a precaution.

Examples - 33-ohm resistors in HF amplifiers. 3.3 K-ohm in audio frequency anplifiers. Doesn't matter if resistors have a little inductance as in metal or carbon film types.

Po = V^2 / 2*Rl

So, 10x the voltage means 100x the power.

Hi,

I am trying to locate a science of cambridge (Later to become sinclair) MK14 computer system.

The computer was avaiable in home built kit for in the UK and from what i am led to believe, most examples were sold to amateur radio enthusiast, as at this time they were the only people experimenting with electonics in the home build environment. (Hence my reason for posting in this NG)

If you have one, or spares, or indeed and sinclair items ie computers, calculators, radios, watches etc, working or otherwise, that you would like to sell, please email me as i cannot regularly get access to newsgroups.

I would also possibly be interested in early home computers from the 1970s and 1980s.

Thank you in advance.

3335. JFET winner: J310 (was Re: Your favorite FET?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-23 00:00:00 UTC
From: "Ralph E. Carter" <carterr@bellsouth.net>
Message-ID: <39034A5F.B258AB58@bellsouth.net>
Source record: 61237

I choose the J310.

I'm not sure the U310's metal case is necessary anywhere for HF, unless
you're pushing its power dissipation spec. I think I would avoid doing
that. For ultimate stability in an oscillator, the U310's temperature
would probably vary less.

If I were forced to use less current, I would use the 2N548x family.
The lower capacitance and higher cost of the 2N4416 are not necessary at
HF.

Wherever a MPF102 is specified, I think you can assume: "Any
small-signal low noise JFET. Trim as needed."
For a basic hobbyist like myself, any old JFET with appropriate specs
would
do fine.

I suppose I'll go look at the MOSFETs now.

I used these resistors for MOSFETs and valves, since early 60's to
cure spurious effects of unwanted coupling between input and output of
the stage, 47 ohm in series with grid and anode for 6AK5 seems to
work, 47-100 ohm for Mosfets
don't think it was W1ICP or W1CER who mentioned this first

>These days you might see ferrite beads used to do more or less the
>same sort of thing.

it might have the similar effect of a resistor with small coil in
parallell, low value at low frequency, increasing at higher, but the
device is certainly not purely resistive, paralell capacitance seems
to be a problem - not series inductance

seems that MPF102 is very loosely specified, gm= 2 - 7.5mmho, compared
to MPF105 (2N5459) which has 2-4.5mmho, and J310 with 8-20mmho

could it be that if a device is out of specifications, it is sold as
MPF102?

EI was the first electronic magazine I ever saw or bought. It was the
Jan 1971 issue. I already had an interest in Ham Radio, and had worked
my way through the electronic/electric books at the children's library,but
I didn't know there were such things as electronic magazines, and I sure
can't remember why I noticed them that particular time.

The other electronic magazines must have been on the shelf next to EI,
but I also can't remember why I chose EI over the others back then.

The non-technical stuff like Uncle Tom's Corner, and Wayne Green's column,
were certainly useful for the first few months, because I sure
know much about electronics at that point, and they gave me something to
read and to continue to get the magazine.

About a week later, I got my first issue of Popular Electronics, and
then Elementary Electronics, and I received my first issue of QST in
April of that year, so I must have moved forward fairly rapidly.

Electronics Illustrated died off at the end of 1971, with an editorial
saying how it was too difficult to keep going, and it would be merged
with Mechanix Illustrated (published by the same company) and how
it would be all for the better. There was a very small "Electronics
Illustrated" section in the following issue of MI, and it lasted for
a few issues, complete with "Including Electronics Illustrated" on
the cover, but it hardly compared with the standalone magazine, and

sure didn't last very long.

I suspect that's one reason EI isn't remembered as much as PE. Popular Electronics lasted longer, and just maybe EI started after PE.

I was able to get a good collection of back issues of PE and EI from the decade before I first bought an issue, in the next year or so. That decade seemed so long in the past at the time, but nowadays a decade seems so much shorter.

I'd have to say that I liked PE better. It seemed to carry more advanced material, and I suppose that's one reason that EI had wiring diagrams. But if you look over a decade of a magazine, there is an awful lot of repetition. "We haven't run a GDO article for a while, so we'd better buy one now", or one of the regular authors wanted some money so they sold a project that was just a reworking of one they wrote before. But there were stand out articles in EI, as there were in PE, construction articles that showed something new for a change.

I look at the magazines now, be they hobby electronic or ham, and they don't carry the same feel that they had back when I first discovered them. I'd like to think that some of it is because I discovered them at the age of 11, and they were exciting because it all seemed so new. I'd like to think that I find today's magazines less attractive because they've been a part of my life for almost thirty years, that I am much older, and that the repetitiion inherent to such magazines have just worn me down. I'd like to think that the hobby electronic and ham magazines can be as appealing to the newcomer, especially the young, as they appealed to me back in 1971.

>
Well, they didn't take fifteen years to get to college. The stories stopped
appearing by the mid-1960's, and they had made it to college.

As I said in the "WTB" thread, the stories were a chance to educate
without being really technical. There was one episode when they were
in college, and they were asked by the college radio station to track
down a "bootleg" station interfering with it. The college station
transmitted using the the power line as the distribution system, so
before the adventure started, we were treated to an introduction to
the way it was done. The adventure wasn't first, with the electronics
secondary (as it was in say the Hardy Boys adventure where they suddenly
were hams), but the adventure was a way to describe something technical.

In many of the stories, people would come to them with problems because
it had become known that they were "electronic experts".

Other times, they were minding their own business,and got into a situation
where they used electronics to save themselves. The one where their car
was overtuned and they used the electrical system to send morse code
using sparks, or the one where they were locked into the back of
a gas station by criminals and they used their knowledge of telephones
to make a makeshift telephone from a speaker and transformer out
of a tv set (and shorting the phone line rapidly to dial) were
examples of that.

The third category might fit into the area of pranks, like the time
they learned about snow making, and tried it and then couldn't
stop the snow, or the time when they set up a fun house.

The best ones semed to be the ones where John T. Frye ahd read something
in a technical journal, like about magnetometers, and used that
as a basis of the story, because he was bringing fairly new ideas
to the hobby magazine.

I thought there were warnings 35 to 30 years ago about the wide spread
of the specs on the MPF102. I recall a letter to Ham Radio that pointed
this out, and my recollection is that it pointed out better choices
from Motorola, almost as if they had sorted devices out into better
specified parts.

Of course, another way to look at the MPF102 is that the number is used
as a generic descriptor, like the 1N34, 1N914 and 2N706 in the old days,
and more recently the 1N4148, 2N2222 and 2N3904. I imagine there were
similar common devices in Europe. Someone chose these in the first
place, and others used them elsewhere because they were already in
public view. After a while, you could buy these devices everywhere,
reinforcing their use in future projects. But after a certain point,
the part numbers became so common that they were a description of
what was needed, ie a general purpose part with a certain range of
specs.

Every time I see "1N914" or 1N4148, I just pull a small signal diode
off a scrap board, unless there is something really special about the
circuit it's used in. Likewise, in most cases for common silicon
transistors, I know I can pull a similar transistor off a junk board.
Of course, I know enough to be able to look at the circuit and
see if there will be a problem, such as frequency range or some extreme,
so that I might be safer using a more carefully considered replacement.

And once a part becomes very common, many will demand it rather than use it to define a type of part. So I suppose some surplus distributors might start marking or remarking generic parts with "MPF102" or 2N2222 regardless of what they were supposed to be originally, simply because they know that those specific parts numbers are commonly bought. These companies are selling generic parts, so why not put a generic part number on them?

Slightly off topic: gass state amp

I would like to build, or even just buy a home brew vacuum
tube HF amplifier. Specs:
input: 5w
output: 30 to 100 w
freq: 3.5 to 30 MHz, or any ham band therein
type: linear
Output needs to be clean enough for current day ham use

Would consider buying or building a solid state amp
as a second choice.

Thanks.

This was probably covered a million times on this newsgroup but I have not been able to find it. I am looking for a spec sheet on this RF chip. I want to modify the mixer section on my Ten Tec Century 21.

Went to the Signetics web site but they don't have any data sheets there. I was also told that Radio Electronics had an article by Joe Carr back in 1997.

Any help would be appreciated. -B

From: py1ll@my-deja.com
Message-ID: <8e1ssi$qk7$1@nnrp1.deja.com>
Source record: 61162

Suppose a rf wave entering two different buffers. The first buffer output is AM modulated with the signal S1 and the other AM modulated with the signal S2.
Now, both modulated signals are half-wave rectified, keeping the positive semi-cycles of the first one and the negative semi-cycles of the second. Now, if we sum the two rectified waves, we get a rf signal with a positive envelope S1 and a negative envelope S2.
Let's radiate this rf signal.
Affirmative: "In the receiver end, if we use a diode detector with one polarity, we will detect the modulation S1 and with the other polarity we will detect S2".
The questions are:

1 - Is the above affirmative true, that is, can we transmit 2 (two) different signals S1 and S2 simultaneously using this AM modulation scheme?

2 - (no matter if the answer is positive or negative) Why?

3 - Will this method work for conducted signal, that is, not radiated but through wires?

Tom OM,

The Boy Electrician! Brings back fond memories. I found a copy in
our small town library when I was 11 years old, and I've never been the
same since, HI. I actually built a spark gap transmitter using a Ford
Model A coil, and Vee antenna, in 1952. It ripped up every radio (and
the very few TV sets) in the neighborhood. It thrilled me (after all,
that meant I was really TRANSMITTING). I have never seen a copy since.
Maybe now I can find one.

It won't work. Just imagine what happens in the demodulator if one channel is unmodulated.

What happens is that the pair of audio waveforms modulate each other. Better way is to allocate the single transmission path to each of the audio channels in turn. It's called Time Division Multiplex.

I know what you mean about that book. It seemed like I had it perpetually checked out of the library. I built the telephone system described in the book in about 1949. Also built the Tesla coil with the twin antennae, and a few other projects.

I believe all the Alfred P. Morgan books have been reproduced, including "The Boy Electrician." Check Amazon. I know I've seen them at hamfests too.

When the TV show McGiver first started, I thought it was a great departure from the shoot 'em up shows where guns and fist fights were the way to solve problems. Finally a show promoting using your brain (and science) instead of brawn! Unfortunately, as the show dragged on it just ended up into very predictable fist fights anyway.

Many thanks to the people that wrote back. I was moving my office this
past week-end, and my computer was off-line for a few days. I'll be in
touch with you guys that so kindly offered to exchange information on
those great old circuits. It's true that modern semiconductors (Mosfets
and the like) will perform better than those vintage devices, but wasn't
it a thrill to push a CK722 to oscilate at 1Mhz in those AM broadcast
transmitters? Weren't you mesmerized by a SB-103 pulling in 10M CQ's at
a time that junction transistors struggled to reach 5Mhz? Well, I was
and I guess I'm trying to go back to those worry free times riding on
those old regenerative circuits.
Thanks again.

>Usually, there is a 'magic' source resistance one can use that makes
>the transconductance stable, over all production variations.

No there isn't. The stability just continues to improve as
it increases. You typically have to waste 3 to 5 volts across
the source bias resistor to get a design that holds the bias
within a 2:1 range for all possible variations in the FET
parameters, since the specs are (in 99% of the cases) loose as
a goose.

That is why the BF904 is such a breakthru. It requires NO source
resistor, yet the bias is stable to something like 20%. It has
a little bias controller built in. Clever!

Last time I checked, the Kanga website indicated the KK7B R2 kit is not avaliable.

Apparently, they are going to replace it with the "R2 PRO" which is not ready yet, but close enough that they've stopped carrying the original R2 kit.

That should be a neat trick.
Now if you can get a motor with this same efficencey you could hook it all
together, give it a spin and it would run forever.

The resistors work with added reactance such as a paralell coil or through
stray reactance to suppress the VHF content. They would do little by
themselves.
```

If you are in the mood to build super-regens, please try my new circuit.
I made a couple of prototypes, but would like someone else to try.
Sorry, you cannot use a CK722 on this one. It is a broadcast band
FM radio (100 MHz) and requires a 100 MHz FET (J310, 2N4416). The
radio is a 1 transistor super regen, plus audio amp. Let me know
if you have any success.

http://www.somerset.net/arm/fm_only_lowtech.html#projects

Hello--

Some years ago, someone wrote an entry for a QST "Hints and Kinks" column describing various strategies for creating weighted tuning knobs; these included filling the grooves in the rear of a suitably-sized knob with...

--solder melted in a few drops at a time;
--mixing lead or steel shot and white glue or epoxy cement.

The NE602A is now the Philips SA602A, you can down load the data sheets here

http://www.semiconductors.com/pip/NE602AD

you can get a lot of app-notes here

http://www.semiconductors.com/cgi-bin/search/search.pl

and you can by the old NE602A for $2.25 each here

http://bgmicro.com

Another source of kits would be nice.

However, let me make a suggestion: Hire someone else to write the
manuals! Preferably someone who understands "sentence" and "paragraph".

Dave

The DNS system was hacked and www.arrl.org got redirected to a
different site. arrl.net wasn't affected.

You can reach the League's web site by pointing your browser to the
correct IP address instead of the FQDN:

http://209.140.206.201

Source record: 61068

If the plastic knob is hollow, try filling it with a mixture of fine lead or steel shot and epoxy glue. Did this on an old Heath SB-102, and it worked great.

3410. Re: QRP final transistor

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-25 00:00:00 UTC
From: Brendan K Callahan <god@pcpartner.net>
Message-ID: <8e5m4b$1eu$1@ins21.netins.net>
Source record: 61073

-----BEGIN PGP SIGNED MESSAGE-----

I am using the 3553 in my QRP rig (I managed to break the leads off
of the original transistor for the kit), and so substituted the 3553
with a heat sink. It works fine, and puts out a tad more than the
original transitor (1w/1.25W). I'm sure I could boost that to 2, or
even 3 with np, however, my antenna is not matched well (about 4:1),
so I don't want to push it. But 3553s are cheap, so if I fry it with
bad matching, while learning how to make HF antennas for 80m <shrug>
who cares.

It has been through 18:1 SWR matches, and survived quite nicely. I
recommend it if you think you might fry one <grin>.
(The rating for it is 5w dissipation--a big heat sink may get you
that, but have it tuned first)

Source record: 61074

```
-----BEGIN PGP SIGNED MESSAGE-----

There seems to be a serious lack of info on the web for
repairing/building rotor control boxes. In particular, I have what I
believe to be a AR22 (I rent the house--it came with it)on a mast--no
box of course. Anyone have the schematic for this? Or any other
control boxes? I am thinking of putting up such things on my
http://www.qsl.net/k0ees page.

Also, is there a simple way to test the rotor (such as 12VDC across
two particular wires), before I try to build a control box? It has
an 8 wire cable attached to it. If necessary, I can grab a digital
pic of it and post it if anyone wants to confirm the brand/model for
me.

3412. HTX-10 mod/CW question

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-25 00:00:00 UTC
From: Brendan K Callahan <god@pcpartner.net>
Message-ID: <8e5ndp$7hv$1@ins21.netins.net>
Source record: 61075

```
-----BEGIN PGP SIGNED MESSAGE-----

I have a HTX-10--nice radio for it's price, and was a great radio for
my entry onto HF this January.

I passed the 5wpm, and I really want to work on it, so I don't lose
it. 10m seems to ahve better oppurtunities for me at present than
the 80m QRP rig I built.

1) Anyone ahve a clue how to possibly modify this radio for CW
operation?

2) What is the difference between unmodulated AM (mic switch shut
off--I homebrewed a Sony studio lowZ mic to work with this as a base
station--everyone says it sounds way better than the stock mic)
(picture is at www.qsl.net/k0ees/ ), and CW? Am I violating anything
by keying the PTT switch in AM mode on the CW portions with the mic
shut off?

73 de K0EES/AE (and no, I won't touch the extra/Advanced CW bands
until I get a faster speed--however, I have no problem using the
Extra Phone bands--seeing as I *can* talk 20wpm <grin>)

>we will detect S2".

To problem with radiated signal or AC coupled signals is that you
loose the reference level, "0" level, thus, you can not separate S1
and S2 independently, since the reference level would be midway
between S1 and S2.

>3 - Will this method work for conducted signal, that is, not radiated
>but through wires?

If you have DC-connection through out the system, then you have a
solid reference level and S1 and S2 could be extracted simultaneously.

Usually, there is a 'magic' source resistance one can use that makes
the transconductance stable, over all production variations.

I only use fets for low-freq, hi-z circuits, and dual-gate mosfets for
their neutralization at vhf. For all else, bjts are superior, and have
low production variations when used properly.

I made a one-transistor super-regenerative circuit on the weekend. It used
a BC548 and was tuned for 27MHz. You can see the detected noise directly
on a cro. It was self-quenching at 10kHz. It also worked as an 80dB log-amp.

Actually it appears that the DNS serving arrl.org died. Earlier today
it could not be reached and the arrl.org entry appeared to have timed
out, but now nslookup actually returns the address of one of the
nameservers serving arrl.org (s1.netfirms.com), which appears to have
been hacked. If you access www.arrl.org using the CORRECT IP address,
you will see that it is still there:

3420. Dick Smith Commander 2mtr. kitset output power?

Newsgroup: rec.radio.amateur.homebrew

Source record: 61192

Hi,

I've built a 2 mtr. kitset 'Dick Smith Commander' that somebody had laying around for some 15 years. It works fine, but I think I'm not getting the right output power, according to the manual it should be 10 - 15 Watts, but I'm only getting about 5W.
Anybody around that has got one and give me some pointers??
Thanks
Gerard, ZL2GVA

The 'break even' point of a car alternator is at a higher RPM than
you want it to be. I found that rewinding the alternator with more
turns of smaller wire, and making it a 6 pole single phase worked
extremely well. 600 shaft rpm gave more out than in.

Build a 700Hz-800Hz audio oscillator. Put the output of this tone into the mic input (you will have to level adjust the tone). With the rig in SSB mode, put it in transmit and key the oscillator with your key.

Hello,

I have a qty of 75 microwave sources.

I was told that they are in the 11 GHZ range.

These units have a 1.8 Ghz or so DRO PLL
and multiplier chain.

The output frequency is around 12Ghz. The PLL
is a Fujistu MB1502.

It looks like the unit has 2 outputs at 12Ghz and
a sniffer port for the 1.8 Ghz DRO.

There is a Motorola 68HC811 microcontroller and
a "D" connector for power and communication.

There is also a 10MHZ TCXO made by NDK on the units.

I have high resolution jpeg pictures I can send you if interested.

I am asking 25.00 each or two for $40.00 including shipping in the US.

These were made for P-COM. and were manufactured in
96 and most of them are new. I haven't had a chance nor the time to check
them out. They are 3 by 3 by 1.5 inches.

If Interested please and want pictures send a request to

Email norman@pcseng.com

Jim OM,

You can get the bare board from Kanga. That is what I did. The receiver can be built easily from readily available parts and/or your junkbox. I usually find that ready-made parts kits are more expensive than my own acquisition cost for parts, and also using my own parts, I can hand-match certain components (such as the audio phase shift components) to maximize the sideband suppression; I am getting -50dB on my R2. You can also make your own balanced mixers at lower cost, using hot-carrier diodes, instead of purchasing ready-made mixers. Now that I have built one receiver, I think my next one will have my own PC board layou also, which I can optimize for my particular situation.

73 and GL,
Don, W6JL

>transisters. Because of my poor vision, I tend to melt my glasses and
>burn my nose a lot too.

Suggestion #1: Use machined pin IC socket pins. You can clip them out
of a plastic dip socket frame and solder in the pin and then later plug
in the transistor. They won't add that much stray capacitance used by
themselves. You can get a handle on them by putting a 24 or 22 gauge
solid wire in the socket part. Make sure the wire is small enough not
to spread the insert.

Suggestion #2: Go way back in time. Digging out the oldest Handbook
I've got (1962), the 6 meter converter in the VHF Receivers chapter
uses Nuvistor tubes, which would be just as much trouble as transistors.
And a heck of a lot more expensive these days.

Here's one of the best (of a very few I've found!) web pages on Litz wire. This is the top page...the details are buried in pages under it. For example, they list 8 different types of Litz wire construction.

http://www.neewcweb.com/litz/litz.htm

Of course, the useful frequency range depends on what you are doing. If you're involved with high power, Litz wire could be useful to down into the audio range, and if you're working with tiny stuff, it could do you some good above 2MHz, though probably not much above. They use a LOT of Litz wire at the megawatt transmitting station on ~20kHz a wavelength or so from here.

Cheers,
Tom

What Dale is describing is not MCW. You would be correct if you
were using the AM mode. When you are in the SSB mode, the carrier
and one of the sidebands are suppressed and all you transmit
is a signal that is offset from your center frequency, by the
audio oscillator frequency.

This was, and may still be, a common way of producing RTTY
signals. Shift an audio oscillator 180 Hz and plug it into
the microphone jack.

It is a good idea though to make sure the audio oscillator puts
out as pure a sine wave as possible. Otherwise you will be
also transmitting the harmonics of the audio frequency. A good
low pass filter would probably be wise.

I'm a little out of touch with the newer rigs, but many of the
older commercial rigs used this very same method for their CW
mode. Usually they used a phase shift oscillator that puts out
a nice clean sine wave and is very stable.

> > >

Well, strictly speaking, if it's not modulated, it's not AM.
On/off keying of a carrier is CW, whether you do it from a key
input or the PTT switch. You may find, however, that the built
in delays are to slow to do this effectively. It would be best
to set up a schedule with a friend and try it out.

Another thing you will run into is a problem with the receive
bandwidth. Without an external audio filter the SSB mode
bandwidth is going to be to wide to work effectively. Common
bandwidth for SSB is about 2.1 to 2.5 KHz. For CW work you
should really use a bandwidth of about 350 Hz. You can still
use it, but you may have to put up with a lot of extra signals.

If I were to suggest something (which means I'm about to), since
you already operate QRP, why don't you just get a nice
15 or 20 Meter QRP rig. These are great bands for CW. 15 Meters
has a nice big novice band for working your speed up.

I have seen old Heath HW-8s for sale lately for about $100. These
rigs run 80, 40, 20, and 15 Meters. I have one myself, and
love it. There are a lot of good older rigs available at
HamFests for good prices. With the change in the FCC rules I
expect them to even cheaper.

> > > 73 de K0EES/AE (and no, I won't touch the extra/Advanced CW bands
> > > until I get a faster speed--however, I have no problem using the
> > > Extra Phone bands--seeing as I *can* talk 20wpm <grin>)

On 10 Meters, the best CW is at the low end, 28.000 to 28.070.
As long as you are General, or above, you are welcome there.

Hi, I need at least one or more Amperex 8163's, must be known good and full output. e-mail me if you have any to sell...73 Lou

3441. Want to build signal generator

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-26 00:00:00 UTC
From: Rick Haub <rhaub@midwestmicro-tek.com>
Message-ID: <39075D0A.59AA8855@midwestmicro-tek.com>
Source record: 61096

Subject pretty much says it all. I would like to build an signal generator that goes from about 30kHz to about 10MHz. Can anyone point me to a web site or mag article?

Thanks,

Rick KC0GIX

3442. Voltage doubling, How high can I go?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-26 00:00:00 UTC
From: Rick Haub <rhaub@midwestmicro-tek.com>
Message-ID: <3907637A.230324AF@midwestmicro-tek.com>
Source record: 61097

I've recently come across a schematic for a fairly simple superhet receiver that I'd like to build. Unfortunately it is a British homebrew and requires 250v, easy to get in England, not so here. What I've got is a 1:1 lines isolating transformer rated at 50ma. I think I can just add a voltage doubler to get the 250v. But this got me thinking, will this half my current rating? I assume it will. Also just how high can I practicaly go? I like working with tubes but finding HV power transformers at a reasonable price is pretty tough. Can I just keep doubling until I get the voltage I want, halving the current as I go?

I've seen line isolation using two 12 volt power transformers back to back. In other words the 12 volt output of one is run into ther 12 volt output of a second transformer thereby giving you your original 120v back but isolated. I assume there must be some line losses, I would not think that you get 120v back out but some thing a bit less. Any knowledge on this would be great.

Thanks

Rick KC0GIX

For what use is the 240v power needed? Is it there to give hv to a tube?
Almost all transister based designs will step the power down and/or convert
to low voltage dc before it is used.
Most voltage doubling circuits not using transformers are for low current
applications, less than 100 ma. If you want to wind a transformer a simple 2
to 1 turns ratio with large enough wire to handle the current will allow you
to double or halve the voltage as needed. This will give you a supply that
can handle several amps depending on the windings you use.

I saw plans for a tesla coil once that used step up transformers in series
to get up to the operating voltage. It was dangerous in the sense that the
insulation on the wires may be rated for 600-1000 volts and offered no
protection after several step up stages when the voltages were in the
50-100000v range. You run the risk of arcing thru the insulation and having
very high voltages running loose in your cabinet. There is a reason that
those hv transformers are expensive to aquire, they require more expensive
materials and better engineering than a $1 audio isolation transformer.
thanks, John.

Hello.
Purchase the ARRL book "Solid State Design for the Radio Amateur". There
are several examples of homebrewed signal generators there; you can
scale the frequency to whatever you want; add other ranges, etc.

Hello.
Yes, the volt-ampere rating (about the same as the wattage rating) of the transformer stays the same. That is, if you double the voltage out, for the same rating, the current must halve. You of course can't get something for nothing. You can add doublers, triplers, quadruplers, etc. to get any reasonable voltage, though the complexity of diodes and capacitors goes up fast too. Remember also, the doubled (tripled, etc.) ratings are based on a very light current draw. The voltage really sags under much more than light current draw.
Using back-to-back transformers to get isolated 115vac also works. Again remember the volt-ampere rating rule, and as you surmise, there are some losses, so your final output is not quite the same rating as the transformers (less).
I could also ask why you are contemplating building a tube superhet, when an equivalent solidstate version would be easier. (See aforementioned Solid State Design book for solidstate superhet circuits.)

I remember having a 6m converter that used a 6BE6 penta grid converter. I think the schematic came from a 60s issue of the ARRL handbook. I wasn't a ham at the time but there was 3 guys who talked locally on 6m AM. My intent was to add an RF stage one day but never did.

For sure it doesn't work. Even in a 'DC wire connected' system. This
because this method is extremely sensitive to the presence of
reactances, that is, if an even small capacitance exists a mixing
(intermodulation) will occur between the two channels, prior to
demodulation. When demodulated, both channels will contain S1 and S2,
although with different intensities.

Thanks for the information. Would you have any idea how much current I could get out if I were to use two 12v out/2A transformers back to back? I had two 12v/450mA sitting in my junk box and hooked them up last night with a voltage doubler. I got about 300 volts out with only a 180k bleeder resister across the output, so I know I can draw at least 1.5mA with this configuration. It was late and I was too tired to do much more experimenting but I'll do somemore tonight. I only need about 50mA for this project but I've been looking at some transmitter designs that need up to 600v @ 200mA. More experimenting will tell the tale I think.

I'm reminded of Gonzo when he was ask why he was going to Bombay India to become and actor, he replied "Sure, if you want to do it the easy way".

Actualy (trying not to start the old hollow state/solid state debate) I was going to be a ham 25 years ago, when I was a kid, and collected a lot of tubes, HV caps, sockets and the like (didn't think to grab the transformers, to heavy, DOH!). So I got a lot of that stuff hanging around. And I design embedded controllers for a living and it's nice to go home and do something different. But the biggest reason, they're just so damn neat! I spent my entire adolencent and adult life getting degrees in the sciences and working with electronics and physics but I still stand in wonder at the orange glow of a electron tube.

Thanks for the help Steve, I'm going to look for that book on solid state design, sounds like it has some good test equipment.

Remember that, for a tube radio, there is a filament current to be
supplied. If you rewire the filament circuit (or replace its tubes for
equivalent ones but with suitable filament voltage), you will need a
much smaller current for the +B supply.

Since the secondary is rated at 12 volts at 2 amps, that represents
24 watts. If the transformer has a 120 volt primary, then the turns
ratio is 10:1. Thus, since the current goes as the inverse of the
turns ratio, the primary current would be 2/10, or .2 amps (200
milliamps). Therefore, if we negelect losses, you would have 200
milliamps flowing in the primary of the first transformer, 2 amps
flowing in the secondary of the first transformer, 2 amps flowing in
the primary (low-volage) side of the second transformer, and 200
milliamps flowing in the secondary (high-voltage) side of the second
transformer. Note that the power is conserved at each step. 120
volts at .2 amps in the primary of the first transformer is 24
watts, which is the same as 12 volts at 2 amps in the secondary of
the first transformer, and this is the same as the 120 volts at .2

amps in the secondary of the second transformer.

Now, what you'll have to pay attention to is the losses. While large transformers can be extremely efficient (>99 percent), small transformers aren't nearly as efficient. Thus, what you may find is that at maximum load, the output voltage sags. Plus, the transformers may get rather warm. Part of this heating may come from magnetizing losses (eddy currents, etc.), and part will come from ohmic heating of the windings.

In any case, the 12 volt-2 amp transformers won't even come close to supplying power for the 600 volt-200 milliamp transmitter design. The transmitter requires a power of 120 watts (600 volts times .2 amps), which is well in excess of the 24 watt capacity of the transformers. An attempt to pull this much power from the transformers will result in excessive currents, and this excessive current may lead to a thermal meltdown (e.g., It's no fun to have pools of molten copper flowing about.).

Also, note that the voltage on the output from the second transformer will be about 120 volts RMS. When you rectify the sine wave output, the actual DC voltage will peak at about 170 volts. In actuality, the voltage will be slightly below this due to losses in the transformers, and inefficiencies in the rectifier and filter assembly.

Are you using a half-wave or a full-wave voltage doubler?

I'll also offer a cautionary note about an approach that some people have taken which is not entirely safe. An approach similar to the one you're persuing (e.g., using two transformers back to back) can be used to step up the voltage to a value above the input value. Consider the case where the first transformer is a 120 volt to 12 volt transformer, and the second transformer is a 120 volt to 6 volt transformer. If the second transformer is connected (in the reverse direction) to the output of the first transformer, the output voltage will be approximately 240 volts. But, this is VERY dangerous! The problem is that the second transformer may be driven into magnetic saturation, at which point the losses in the core will be significantly higher than normal, resulting in a dramatically higher heating. Additionally, the 240 volts developed on the secondary may exceed the insulation rating of the transformer, resulting in dangerous electrical leakage.

Orange glow? I hope you meant dull red glow. The filament/heater
in most 'modern' vaccum tubes only reaches red hot temperatures. On
some of the older tubes, it reached a yellow level of incandescence.
Of course, if you're working with gas-filled tubes, such as some of
the voltage regulator tubes, these can produce a quite vivid glow.
Some of the gaseous voltage regulator tubes are filled with Neon,
and emit the characteristic Neon-orange glow while in operation.
Others (0C3?) are filled with Argon, and emit the characteristic
purple glow of Argon. And, then there's the blue glow of the
envelope of some vaccum tubes where it's struck by electrons. And,
of course, this is different from the blue glow of a mercury vapour
rectifier in operation. And, then, there's the cherry red glow from
the anode of a heavily loaded power tube.

You know, that's the problem with modern electronics: There isn't nearly
enough colour associated with it. :*)

(posted this earlier but it didn't seem to escape my ISP black hole...)

Rick,

You really shouldn't need more than 150V or so to run a tube receiver. The only stage where higher voltage matters is the audio output. Unless you're trying for PP 6V6s or more, you can pick an output tube that will provide decent output at a lower voltage (e.g. 6W6, 6Y6, 6CU5). The tradeoff is that these tubes need more heater power, since they need to heat a bigger cathode to produce the same plate current at lower plate and screen voltages. That's not a big deal, though, since filament transformers aren't scarce. I've got a 1:1 isolation transformer PS (capacitor input) that provides about 160V with a fairly heavy load. The transformer, BTW, is actually a dual-primary job so it can be hooked up backwards to give 250V if you want. I'm pretty sure it's the 50VA one that All Electronics has:

http://www.allelectronics.com/pdfcat.html

though I got mine locally.

One way to save on power transformer and choke costs is to build your rigs without power supplys and built a couple of separate power supplies to run your rig-of-the-week. I use the 8-pin Jones connectors for this -- I think they're good up to 750V. I also always provide 12.6VCT for heaters, so I can use both 6V and 12V tubes (as well as the cheap but high-performing TV series-string oddballs: e.g. a 4AU6 and an 8CG7 in series).

Brian,

Yes, it is possible to do full duplex down the same coax. With most
gunnplexers
the other station is offset by about 30 Mhz (or sometimes 10.7 Mhz,
depending
on what IF receiver you are using).

3467. New program SOLNOID2

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-27 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <8ea690$11d$1@neptunium.btinternet.com>
Source record: 61122

SOLNOID2.exe is an updated and improved version of successful program Solenoid.exe which it now replaces.

Computed inductance is more accurate for coils with small length/diameter ratio.

Any number of turns from 1 upwards.

Covers single turns from a loop to a straight wire

Frequency range 1 KHz to 1 GHz.

Output data :- inductance, reactance, impedance at resonance, Q when in parallel resonance, Q when in series resonance, self-capacitance, self-resonant frequency, capacitance to resonate at test frequency, watts dissipated for given RF volts across coil, wire diameter, wire length.

Facilities for fast sweeps in small increments of :- test frequency, coil length, coil diameter, ratio of wire diameter to winding pitch, number of turns, while observing tabled output data.

Self-resonant frequency of solenoids or helices is accurate enough for analysis of home-brewed slinky antennas.

AVAILABLE NOW FROM WEBSITE BELOW. Only 43 kbytes. Download in a few seconds. No self-respecting, do-it-yourself coil-winder, professional or amateur, should be without it.

I currently have up for auction at eBay a nice copy of the "Transistors Handbook" by William Bevitt, published in 1957. The 410 page hardbound book is in very good condition, clean with no page tears or pen marks other than a previous owners name inside the front cover, and a strong binding. Everything you could ever want to know about transistors. Opening bid is $8. Auction closes 5/2/00. Thanks.

Dave

>Steve AA7U

Just as a general FYI on simple tube superhets, the simplest design (for HF) consists of a converter tube (6K8, 6SA7, 6BE6) driving a regenerative detector and audio amplifier. These latter two stages were usually combined as a single dual-triode (6C8G, 6SN7, 12AU7) so the whole rig used two tubes. This format was in radio handbooks from the mid '30s to the end of the '40s or beyond. One of the members of the glowbugs list, Baz ZL1DD, says they were an excellent and popular improvement to the classic regen, since they avoided all the problems of connecting the detector directly to the antenna. Frank Jones W6AJF called these "super gainers," an extension of his term "gainers" for regens (in particular, a detector and one stage of audio).

For cheap BC reception manufacturers would sometimes produce a stripped-down All American 5 radio without an IF stage -- just a converter going through an IF transformer to the (envelope) detector. Don't know how popular those were, given how much gain and selectivity were lost in leaving out the IF tube and second transformer.

OTs and others, feel free to correct any of the above...

73,
Mike, KK6GM

One difference is that the K2 is pretty much ham band only- with small excursions above and below each band. However, the major difference is that the K2's receiver is in a league of its own. None of the receivers you mentioned have specs to compare with the K2. In addition, if you have ANY interest in portable operation, the K2 will draw AMPERES less on RX. In its battery save mode, receive current can be well below 200mA! The internal battery makes portable operation a snap. The NB is the best I have used- reminiscent of the Drake 4 line's NB.
Finally, the QSK is silky smooth- so much so that I sold my Omni VI+ after running the K2 for a month. I should add, I only work CW, but the guys running SSB are getting rave audio reviews.
The Elecraft support is as good as their receiver. 100W PA is a planned option as is a 6M transverter- stay tuned- these 2 West coast engineers, are showing the off-shore guys how to design RF gear the right way. I have no affiliation with Elecraft other than buying everything they design.

This was done many times in the early 70's. Many counter culture magazines had homebuilt projects. It's a lot of work to say the least!

Today you can buy a unit - blades and built in inverter controller for less than $600. Just add a battery and a pole and it's done. A Microcomputer (of course) controls everything.

Even has a shutdown governer for high winds.

You might consider solar - again you can buy units already pre-built that includes everything including the paper work for the building inspector. Technology has taken off and prices have dropped considerably since the 70's.

Suggest you buy Homepower magazine. It comes out once every two months. You can read about all the latest and greatest. Stuff the power company would rather not have you know.

With QRP wind/solar power is a natural (pun intended)... and not just for field day only....

Now if someone would only come up with a solar powered motorcycle!!!!

Ed,
Device manager won't remove it. Each time you boot Plug and Play locates all the connected devices. You will need to go into the bios and disable the PS2 mouse port, and then the PS2 port won't be active at boot, and you should have your IRQ 12 back.

From: John Buck <kh7t@arrl.net>
Message-ID: <3909D835.22F3862D@arrl.net>
Source record: 61133

The main differences.
A better receiver. excellent selectivity and blocking range.
excellent human interface.
Compact complete station, wide range antenna tuner, swr and power
monitoring, Battery included option.
10 to 15 watts output vs 100
Not general coverage receiver but is ham bands plus.
You built it and you can trouble shoot and fix it.
Price is similar to the pre built stuff if you include all the options.
This gives you a far better rig.
Coverage does not include 6 meters, I am not sure on the other radios.

Note that the basic price is a cw radio, 80 - 10 meters.
Options include ssb, auto tuner, 160 meters, battery etc.

The 15 watts will not drive FCC compliant QRO amplifiers to full
output. My SB220 needs about 40 watts drive for full output. So my
maximum signal may drop to about 400 watts while using my K2 to drive
the Amplifier.

A good antenna is a far better investment than a power amplifier. I
have both but enjoy the antenna more than the amplifier. The amplifier
is usually off except when attempting to crush a large pile up on a rare
DX station.
Even then I usually stay in the "low" power amplifier setting.

My K2 is in the mail, my current radio is a TenTec Omni VI. I expect
the K2 to perform as well as the OMNI except for the 6 db less signal.
1 S unit.

73,
John KH7T

Contact the following for a catalog of books on all "old" electronics topics. Their typical catalog will have numerous early books on spark technology (do those two words go together). Some are the do-it-yourself type for youngsters, hams, and Scouts. Others are the engineering or theoretical type for ship and shore stations. And some are historical or other themes. Good company, great books!

3484. Wanted: Curve Tracer To Test Homemade Xsistors

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-28 00:00:00 UTC
From: " H. Peter Friedrichs" <NOSPAMpfriedr@azstarnet.com>
Message-ID: <390A60DA.8AF23F0C@azstarnet.com>
Source record: 61139
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics,sci.electronics.components,sci.electronics.equipment

Hi to all:

I have begun experimenting with some homemade (point contact)
transistors. Transistor action, while perfectly evident through current
measurements, has become troublesome and tedious to with multiple meters
and power supplies.

What I'm really looking for is a curve tracer, specifically the modular
type that can be connected to a common o-scope to to display curve
families.

Anyone out there have one collecting dust in their ham shack or storage
closet? Willing to part with it for a reasonable sum? Remove NOSPAM from
my address to email.

BTW, if you'd like to see a few pictures, check out these URLs:

http://www.azstarnet.com/~pfriedr/transistor/xsist1-w.gif
http://www.azstarnet.com/~pfriedr/transistor/xsist2-w.gif
http://www.azstarnet.com/~pfriedr/transistor/xsist3-w.gif
http://www.azstarnet.com/~pfriedr/transistor/xsist4-w.gif
http://www.azstarnet.com/~pfriedr/transistor/whisk-w.gif

The last URL is a photomicrograph of the electrodes in the transistor
shown in the first URL. If you are patient enough, look at 'em all.

Thanks in advance.

Pete

An easier way would be to get two 115v 1:1 transformers and connect the
primaries in parallel and the secondaries in series (right phase of course)
and then you have 115v in and 230v centre tapped out. Just put a bridge
across the 230v bit and some reservoir caps and enjoy some real tube radio!!
Cheers de Alan G3NYK

Source record: 60995

Hi Ed,

To me, the "serial mouse" really is a PS2 type mouse because serial mouse does not have own IRQ assigned and it just use whatever IRQ assigned to your Com port (IRQ 3 and 4). And the Zip drive you have looks like a SCSI version because if you have Parallel port Zip drive, you don't have to free-up IRQ12. Also, there is no 'parallel mouse' and all mice are either serial or bus. What you meant 'serial mouse' really means a 'bus mouse', and what you meant 'parallel mouse' really means a 'serial mouse'. The reason why I say like this is, most brand name PCs use bus mouse, which is also called PS2 type mouse. OK. Let's get clear from now.

You can disable the PS2 mouse port from the BIOS setting. Check the manual and it will list stuffs in BIOS and you can easily change the setting. Next time you delete the device and reboot, you won't see it any more. The Zip drive might come with an interface card, which is a simple SCSI adapter. From Device Manager, high-light the icon 'Computer' then click on Properties, and it will list the IRQs in your computer. Make sure IRQ 12 is now free (not listed). If you don't see IRQ 12, it is the time you can install the Zip drive adapter in your PC and install software for the Zip drive.

I hope this helps and please send me an e-mail if you have any question. 73,

Christopher VE3UVT

Anyone interested in Marconi's rigs needs to get a copy of Peter R.
Jensen's truly excellent book "In Marconi's footsteps: Early Radio."
Jensen is a ham (Vk4AQJ and G4GZT). In his book he visits all of
Marconi's transmitter sites and describes in detail the construction
of replica equipment. Published by Kangaroo press in 1994.

That seems to be a common sentiment, but it really depends on what your definition of "full duplex" is. Physically you can pretend you have a full-duplex link, but logically you can't receive and transmit valid data at the same instant, without a complex system at the IF end to cancel out the FM modulation you're applying to the transmitter (which is also your receiver LO).

Hardcore stuff! Haven't seen anyone build their own transistors before.

The latest Tucker Electronics catalog shows an inexpensive and
nifty-looking curve tracer from one of the Asian manufacturers -- you
might have a look on their web site. eBay is certainly a good
suggestion as well for digging up one of the old Tektronix jobs.

Lottoman,
Look around on the firewall, see if there is a plugged
access hole. If so, cut out the 'stopper' enough to feed
a power lead through it. If no access hole, drill one large
enough for the power lead AND a rubber grommet.
There are access holes 'all' over a vehicle, just gotta
find one....

> Mike, KK6GM

I won't go into the debate of performance, since how well something
works realy depends on the design.

But the most immediate reason that comes to mind against using tubes
is that there is more formality to building with tubes.

But then on second thought I realize that's not true, and I figure it's
worth adding some comments.

When I picture tube equipment, I picture an aluminum or steel chassis,
and the need for heavy metalwork, and something that really isn't open
to changes.

So let's change the situation. Someone mentioned making the power supply external, so it can serve multiple purposes. A further advantage is that a power supply stays constant, whereas the RF design may be something someone wants to change. And once you've moved the heavy transformer elsewhere, tube components tend to be as light as solid state components.

Then you get rid of the chassis with the holes for the sockets punched out. Build on circuit board, with the chassis inverted and used only as a cover. Just as with solid-state equipment, the copper on the circuit board supplies a good ground surface, one that can easily be soldered to. And if something is changed, it's a simple matter of soldering a lead to some other point on the circuit board. It is a lot easier to work circuit board than to put tube socket holes in an aluminum (or steel) chassis. If you scrap the whole thing, the circuit board is cheaper than a new aluminum plate or chassis.

Once you have the good solderable ground surface, one can actually be more creative. Do the IF transformers have to be mounted on the top of the chassis, with associated metal work, or can they be mounted on the underside of the circuit board where it might be easier to mount them?

You also gain the ability to put in a lot of shielding, by soldering pieces of circuit board in the appropriate places.

None of this is new, it's common for solid state work, but it never really caught on during the days of tubes, and I sure haven't seen anything along these lines in recent years.

This scheme also allows for modularization. Instead of one large piece of circuit board, use a number of pieces that straddle the chassis. Then if you need to do major reworking of a section, you only scrap a bit of the work.

Or you can build up different modules, and try them in turn until you get the results you want. Or make the unit multi-purpose by switching in different modules.

This sort of construction makes for starting simple, and then working up. Build an audio amplifier. Then build a regen detector. Once you've played with that, then add a converter ahead of it. If you find you need IF gain or filtering, then you can add that later. If the regen detector doesn't work out, then replace it with a selective IF strip and product detector.

It seems to me that one inhibition to building is that whole concept of having to make it all nice and neat, and start with the finished product (or start simple, throw it away, and build something better). Once you accept that it doesn't have to look commercially built, you will probably get further. And once you get over the idea of putting it all in one box, you make it far easier to perfect. Or cheat for that matter; people will buy expensive external VFOs, or did back when they had to be external, but you don't often hear about someone buying an external VFO for an old rig, and using it with

a piece of homebrew equipment.

3513. Slide-back circuit (detector) for Hellschreib?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-30 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <390cbc3a.7528208@news.online.no>
Source record: 60945

Slide back detector has better zero reference for two-tone RTTY, but not for FSK according to some IARU paper for for 1975 conference, RSGB wrote in length about using 850Hz shift with two tones instead of FSK

Have seen some notes about the slide back detector for RTTY, but it is almost 30 years ago, but time constants may not be optimum for single frequency CW receiption

I use MC1496 quadrature detector and need a circuit to add the slide-back as a post detector facility, is any circuit diagram available for this?

Well before this gets out of hand I'd like to add my ideas.

The two windings are the same impedance so it makes no difference which is used for which. In many cases the audio side impedance is higher but not here.

The direct current in the two windings will tend to cancel so I wouldn't worry about it.

The difference between a 10k and a 5k winding has to do with the frequency respoinse. In other words, if you use a winding at an impedance far from its design center, you will find the low or high frequencies of the audio will be lost, depending on which way you go. Further, the excitation current of a 10k winding will be less than of a 5k winding on the same core. The bottom line here is don't worry about it as long as you are in the general ball park. A 'mismatch' of 2 to 1 isn't enough for concern. In transformers, bigger is usually better.

Remember the good old days ?
When every electronic store in the country.
Had a Heathkit product on their shelf.
Where every radio enthusiast. Had a project half finished, sitting on his desk
Not forgetting that two thirds of the radios, on the market.
Were homebrewed, and not those fancy new electronic gizmos.
Well there is a new company starting up in Hamilton Ontario,
In addition, they will have kits for everything, from kits for your kids.
(Like a simple blink flasher) Including a kit even for, Grand dad's strange hobby.
For dad. A QRP transmitter to use in his station at home.
For Mom, a home brew Big boy vibrator kit,
For sister, the Intro wobble kit
Moreover, accessories too. Be it a DSP or even an antennae tuner.
It will be coming soon! Watch this newsgroup, for more info.
When it starts pass, the word around, finally the old will be new again.
Would not you all like a kit to say. I built it myself.
Well if you do buy a digital, tape recorder kit. When you have assembled your kit.
You can record this message into the microphone
I BUILT YOU ALL BY MYSELF. It will say back to you.
Yes and that's why you live alone

This is not exactly help, however, look for 'all' the articles for
4CX250 amps. There are hundreds of articles. The 150 is the little
brother of the 250. It is 'plug and play' except that you must run
lower plate and screen voltage.

3520. Cheap 455kHz SSB filters?

Hi all,

I'll make an 80m SSB transceiver, and possibly make it a kit,
after i get a source of parts that don't cost too much.

Is there a source of 2-3kHz BW 455kHz SSB filters that doesn't
cost a lot?

Apart from Amidon, are there any other sources of readily
available toroids/IF-transformers?

I'm aiming for 1-10W output, 455kHz single conversion, and
battery-portable.

Yes Dave, you were exactly on track. The feild was wanting about
2 amps at 12vdc to get the ball rolling. After my rewind to single
phase, and using 4 diodes instead of 6, i got breakeven at 600 rpm.
Also, you can do many good things with the single phase winding and
a few transformers. Like step up the voltage to send to your home
which is normally a hundred feet or more away.

3522. QRP RIG COMPARISON

Newsgroup: rec.radio.amateur.homebrew

I have decided to build my first rig and have found plenty of rigs to chose from. I want a 20m rig but the choices are overwhelming. I have found the DSW20, SW20, OHR 100, GB20, NorCal20, Wilderness Radio SST and Sierra, RedHot20, and TenTec. Is there any articles available on the web or persons with personal experience that can help narrow down the choices as my knowledge in the subject is limited. Thank you

It strikes me that if there were suitable inexpensive 455KHz filters, we would have heard about them long ago.

At 455KHz, most construction articles used either Collins mechanical filters, which of course tend to be expensive, or home made crystal lattice filters made with surplus crystals, preferably in FT-243 cases so they could be ground to the needed frequency.

The obvious "cheap" filter would be a ceramic filter. But in reading ham magazines from the past forty years, I've only seen very vague references about using them for transmitting purposes. The articles that come to mind were more idea articles, to hint at something or to point to such a filter and suggest some uses for them. But hard information wasn't included so it's hard to tell whether there was merit behind the suggestion, and nobody went and took the idea further into a construction article. The filters discussed may not have been really great for transmitting purposes, or perhaps the only reason they were considered "inexpensive" was in comparison with Collins mechanical filters.

Of course, some of the Japanese rigs seem to use ceramic filters at 455KHz for transmitting, but I've never seen prices for the filters alone, so they may not be inexpensive.

Even commonly available ceramic filters, such as the type you find in a lot of AM broadcast radios, don't seem to have been given much experimental treatment. Those would probably be too wide, but I wonder if you could get a sharp enough skirt for SSB if you cascaded some

filters. You can get narrower ceramic filters, I've seen them in CB sets and maybe http://www.digikey.com carries them along with wider ceramic filters. Again, the question is whether cascading will give you a decent filter overall.

I've not seen the actual article, but I have seen mention of an piece about cascading ceramic filters. From a previous post of mine:

"In an old article in 73 (December 1977) about the Yaesu FRG-7, reference is made to an "by Ron Risher VK3OM in the March 1977 issue of "Amateur Radio". He describes... an alternate filter, consisting of four cascaded SFD-455-B solid state filters linked by small coupling capacitors". It might be interesting to someone who can get ahold of the magazine, which I assume is Australian."

It sounds like an idea to look into, though I have no idea of the specs of that filter.

Some people have speculated, and done some testing, in rec.radio.amateur.homebrew about using 455KHz ceramic resonators, which are cheap and fairly readily available, in ladder filters. Doing a search at http://www.dejanews.com will turn up some old posts about the idea.

Of course, once we are talking about ladder filters, one could abondon the 455KHz IF. A lot of work has been done on ladder filters in homebrew equipment, and the interest has arisen because the crystals are cheap, and you only need them on one frequency (unlike lattice filters), and surely because inexpensive commerically made filters are non-existent. A lot can be said for putting the IF somewhere in the HF range. The crystals may be even easier fo find than a ceramic resonator at 455KHz, and you won't have to worry about image rejection.

QST has published a number of articles about ladder filter design, and they've been reprinted in various ARRL books. And I've seen some information about them in RSGB publications.

Why not pick a higher IF frequency? This would allow for a lower freq VFO, and better image rejection. Then you could use inexpensive color burst or computer xtals for the filter.

There are some options for the filters you need; these filters are made by Murata. The cheapest filter is the CFWS-455K, a 6 element ladder filter for about 4 dollars. A better choice would be the CFS-455K, an 11 element ladder filter for about 22 dollars. The problem I have had over the years is buying them in small quantities. The only way I was able to procure them was by ordering samples from Stan Clothier Associates, one of Murata's reps. Murata didn't even want to consider small orders; I know we used to use quite a few of them when I worked at Rockwell, but for critical applications, we used the Rockwell-Collins torsional mode mechanical filters, at about 90 dollars apiece in small quantities.
One final note; Murata assigns a letter code, denoting the bandwidth of their filters. Example:
a CFWS-455E would be an NBFM bandwidth, while a CFWS-455H would be a 6KHz bandwidth for AM, a CFWS-455I would be a 4KHz bandwidth, and a CFWS-455K would be a 2.4KHz bandwidth for SSB. The CFWS series of filters are typically the ones that you see used in the 455KHz IF strip in most of your commercially available radios. The SSB filter in many radios such as the FRG-100, the AOR-7030, and others use something similar to the CFS series.
Normally, I don't usually make a whole group posting, but I have seen this question about filters come up several times on the newsgroups.
One more request I have seen is about product detectors for some of the boatanchors; if anybody is interested, I would more than happy to send a schematic of the circuit I have been using in my homebrew designs. Also, if anybody needs schematics of front-end filters for the 0 to 30MHz range, I can supply schematics for filters that will break this range up into 7 segments. I also have a PIN diode switching configuration that does not require a -V supply to reverse bias the diodes. Too bad I didn't think of this one!
If anybody would like a copy of my latest 0-30MHz receiver design, which uses a DDS for the LO, feel free to give me a shout, and I will be glad to send you the schematics, free of charge.

Hi Russ
A easy to get source for 455 filters would be from Yaesu , Kenwood or Icom. They all use murata filters in there 455 IF . Good radios to look at would be , Kenwood 930 & 940. Yaesu Ft -102 , 757 (1000MP has a 2.7K wide murata filter in it's sub receiver) and many Icom's. You could buy them from the companies as parts for those radio's.

The 4X150A/7034 tubes are electrically identical to 4CX250B's. They are
even rated for 250 Watts plate dissipation. The plain 4X150A may not be.
Look for the /7034 versions. Also, I have found that only about half of my
hamfest purchases of these tubes are good. So, make sure you have
plenty on hand when you are ready to fire up the amp. I am taking a
homebrew tester for these tubes to the Dayton Hamvention sense
I will be looking for some more there. Often you can get them for $5 each
if their condition
is unknown to the seller which works out to usually to $10 to $15 each for
good tubes. If they have any dents in the radiator at all, no matter how small,
don't buy them. Most likely they will have internal shorts. Also, check for the
obvious, cloudy glass around the seal, rattles and discolored radiators. Also,
an ohm meter to check filaments and for shorts is handy.
These tubes life time is very sensitive to filament voltage. DO NOT RUN
6.3 volts on the filament. Keep as close to 6.0 as possible. Or, maybe put in
a relay to drop the filament voltage a bit while in standby. Just a half a
volt will make quite a difference in life time. But, on the other hand they
are still
quite cheap.
One more comment, don't consider grounded grid, zero bias operation.
Their grids
will not take it.
good luck
es 73

One more suggestion in case you do not already have the tubes. There
are some other versions out there with unusual filament voltages that
may be available cheaper. Some years ago I bought 4 4X150Ds at a
hamfest at an amazingly low price. Most buyers were passing them up
because they have 25.2V filaments instead of 6.3 Since I was building
the amp I saw no problem in choosing the filament transformer to match
the tubes instead of vice-versa. However my amp was for 2 meters so I
can't help with HF amp ideas for these tubes.

Hi,

I aquired a couple of tone boards at a local rally- thought to to be CTCSS, but the came without info.

The PCB is around 1" by 1.5" and seems to mount by plugging onto 2 sets of 4 pins- all of which are grounded.

There is no makers name- just a part number B3024B.

There is a single IC S 7116A and one transistor.

There are 7 wires. 2 look like power, one is straight through and I think I can identify the I/O.

BUT I can't see a way to program the tones.

Any ideas anyone?

3539. Audio (modulation) transformer question...

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-30 00:00:00 UTC
From: JGinNY <jwg6@cornell.edu>
Message-ID: <390C9F56.E883C393@cornell.edu>
Source record: 61042
Cross-posted to: sci.electronics.basics,rec.radio.amateur.homebrew

This question deals with audio or modulation transformers, and their impedance ratings:

I am looking at a low-power radio transmitter circuit, which calls for a center-tapped AF transfomer to couple a single-ended, Class A modulator to the plate of a Class C RF amp tube. The circuit requires a 1:1 impedance ratio for this coupling.

The parts list indicates a 10,000 ohm AF output transformer. Only the primary winding is used, in autotransformer fashion. (That is, B+ goes to the center tap of the winding, one end of the winding goes the plate of the Class A modulator, and the opposite end goes to the plate of the Class C RF amp.)

Question is -- if the goal is a 1:1 impedance "transformation" between the two stages, then what difference would it make if the tfmr impedance rating were something other than 10 Kohm? Wouldn't the stated impedance rating be inconsequential, as long as the windings were symmetrical about the center-tap, giving the desired 1:1 ratio?

...or does the 10 K-ohm value refer to the _resistance_ across the winding itself?

In another circuit I saw, following the exact same scheme, the text mentions that the "higher load resistance" side of the transformer should go to the AF amp, and the other side should go to the RF amp. BUT if the winding is center-tapped, then wouldn't the load resistance be the same on both sides of the center-tap?

What gives? -- I don't quite follow this.
could anyone out there clarify...?

thanks!
J.

Hello!!
I have a web page dedicated to the radio hobby here in Tampa Bay Florida. I am in the process of launching a new audio chat network on a channel for amateur radio enthusiasts. The idea is for webmasters to put the small html code somwhere on their amateur radio web page which would be linked all together worldwide. The system utilizes the new HearMe plugin which is a small 80k or so program new visitors of the amateur radio audio chat would download upon landing on the page which has the html code for the plugin. Please let me know if you decide to use the system so I can add your site to my links page to let others know your site is connected to the network. For a demonstration of the system you may email me for a time and date so you can see it in action. To get the html code please visit my web site below. To get further info on the HearMe requirments to have it work click on the help are for Hear Me on my web site. I am in no way affiliated with HearMe and my web site is a noncomercial page.You may also visit my radio page at the url below from 7pm to 8pm eastern time every day I try to be in my scanner audio chat at that time. I look forward to hearing from.
Thankyou
Best Regards
Tim Breckon--

I think this description is about using both windings, not an auto
transformer connection, and not necessarily a 1 to 1 ratio. However,
a 10k to 10k transformer normally has one winding with a lower DC
resistance, because one winding is put on the form first, and so has
shorter turns than the second winding. Both windings have to have the
same number of turns to have the same impedance, though. Maybe they
are talking about this effect.
>
> What gives? -- I don't quite follow this.
> could anyone out there clarify...?
>
> thanks!

> J.

First of all, if the transformer has only a single winding connected, the ratio with the unused winding is pretty unimportant. It might have just as well been a 10kct to 8 ohm transformer. Though, if I was doing what you describe, I would be tempted to parallel the primary and secondary to lower the copper losses. As to what impedance the transformer should have, this is related to the frequency response of the transformer. At the minimum frequency end of the range, the inductance of the winding starts to show up in parallel with the impedance coming through the mutual inductance from the other winding, so the transformer total impedance drops as the frequency goes down further. At the high end of the operating frequency range, the leakage inductance shows up in series with transformed impedance from the other winding, so the winding impedance rises at higher frequencies. The 10k load impedance rating is the one that allows the transformer to be fairly ideal over the specified frequency range. If you don't need the low frequency end, you could use it with somewhat higher impedance signals, and if the high frequency end is not important, you could use it at somewhat lower impedance levels. The impedance rating is just an engineering judgment that takes a whole lot of compromises into account.

I big concern for me with this type of application is the allowable DC bias current the transformer can stand before the core saturates. Does the circuit you are building have some way to balance the current in both halves of the winding so that no net DC flows around the core?

Hello,

I am wondering if anybody would have schematics for a relatively
'easy-to-build.' 144MHz to 28MHz transverter.

Coverage isnt that important. At least 3MHz would be great.

3544. #BGY36 18 Watt VHF RF Amp Module.

If you're only doing audio level modulation, the answer is yes. If
you're doing high speed FSK data or video you may find the
non-linearities of the Gunn Diode to be a problem.

Most folks like to use separate coaxes for TX and RX because it makes
life simpler. However, you certainly can do what you suggest.

Have fun!

Not sure about the specific board or chip, but if it is like other such boards, one need supply power (start of conservative with 5V+), ground the obvious ground plane and start exploring the other pins with a capacitor in series with a small audio amp or speaker.

If no tones are found, take the wire that me be "another V+" and tie it to 5V and search the other pins for audio output like above. If this does not work, now ground that same wire and search for tones again.

Most single chip CTCSS encoders are V+, ground, PTT (either + or - on the push to talk circuit), one pin out for audio, and the "other pins", which are grounded in different configurations to select the proper CTCSS tone. Even without any of the programming pins grounded, there should be a tone output, for no-connection is itself a selection of a tone.

This works for several different tone units I have found in Maxon HT's. Hopefully, someone will recognize your particular chip.

Good luck,
Tim Cadigan, (WC1F)

It seems to appeared on july 77, and details is shown in
Philips/semiconductors/part 6 - april 1982 - "RF power transitors and
modules".. it is an ordinary FM power module covering 148-174MHz -
will also operate within 144-146MHz band with - perhaps somewhat
reduced power output. Believe I used it for a project some years ago

what do you need to know? Sri, scanner is temporary disconnected at
the moment.

3553. Icom U12 as a repeater?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-01 00:00:00 UTC
From: &retired0 <&retired0@hotmail.com>
Message-ID: <390E0EFB.63E9B8E3@hotmail.com>
Source record: 60958

I have an Icom IC-U12 that won't transmit and another
that won't receive. Throw in a mobile duplexer, a pic
processor,
some copper shield boxes,
a desire to build something and voila, a solar powered
repeater.

A little fiddling with the phase detector in the
synthesizer
and retuning on the image and they're on the ham band.

Because it's gonna be solar powered, I need to minimize
power
consumption. I plan to run the receiver in a mode similar
to
"battery save" by sampling the receiver every few seconds
and enabling the subtone decoder only when there's carrier.

I don't have the operator's manual. I don't suppose there's
already a battery save mode that I can just enable?
Has anybody got any experimental data on how long it takes
the synthesizer to stabilize and the receiver to come up
after power is applied? Any circuit mods to speed this up?
Ditto for the subtone decoder.

I already have one of these as a repeater receiver, but it's
AC powered and indoors, so I've no data on sampling
performance
or temperature performance.

Any other suggestions/experiences on using these in a
portable
repeater?

Learning from your experience would save me a lot of
experimentation.

Suggestions?
TIA
mike

I couldn't care less personally, but some people do. There are also
propagation issues with binary attachments (i.e., some news servers drop
them automatically). Best thing to do is sign up at http://www.qsl.net
for a free ham radio home page, like mine (below). QSL.NET has really
made some dramatic improvements in reliability over the past year, and
there is no limit to the server space and bandwidth you're allowed to
consume, as long as it's radio-related.

3558. EEPROM type on CMU161

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-01 00:00:00 UTC
From: "Robert M. Ganter" <hb9dnn@gmx.net>
Message-ID: <8enfpt$2rr$1@bw107zhb.bluewin.ch>
Source record: 60963

Hello,

does anyone know what type of EEPROM is used on the CMU161 memory module? This is the 200 channel memory used in various Standard Handheld Tranceivers (like the C558 or C520).
The CMU160 (the normal 40 channel module) contains a X24C04S, a 4kbit EEPROM from Xicor with I2C interface.
Using the same addressing (i.e. 7bit I2C addressing), an EEPROM up to 16kbit could be used. Assuming that all memory is used on the CMU160 (which is unlikely) a 32kbit EEPROM would be needed. If a 16kbit EEPROM is sufficient, the same addressing mode could be used (and I guess, this is how it works). If anybody knows, what chip is used here, let me know. I don't want to try out with an unknown chip and fry my handheld...

Any help is very appreciated.

73

Robert

I'm always interested in seeing new circuits. I've been thinking of
doing a webpage for receiver designs.

Hmm, i didn't know there were 'single' resonator units for 455kHz.
Does anyone know what the unloaded Q and frequency tolerance is like?

I figured that if i made a 2.5kHz BW, 1dB ripple cauer-tchebyshev
filter with 3 poles and two zeros using isolated resonators, the
highest unloaded Q i need is 1200. To make the same filter as a
passive ladder network, i'd probably need a Qu of 5000-10000. The
other problem is that the tolerance of resonator resonant frequency
is quite small.

I've thought of making my own resonator units using a glass marble
with ferrite slugs glued to opposite 'sides', coupled with dc-biased
coupling coils. Three separate resonator units would be lightly coupled
using small shunt inductances. However, its really too fiddly to use for
kit constructors. Also, difficult frequency trimming would be needed.

I wanted to make the if strip using standard 455kHz if-transformers,
and more gain with fewer stages can be got at lower frequencies. I
can get 35-40dB gain from a BC548 transistor at 1mA using transformers,
and they're easier to get and have a nicer agc characteristic than ics
i know of.

Fascinating....I never thought I'd see someone build their own transistor. Keep up the good work. Incidently, what did you use as semiconductor material, and how did you fabricate it? Have you doped it at all?

Tsvetan:

May I make a suggestion? If you want to get business from the States (I see you're located in Bulgaria), post some verifiable (USA-based) references from satisfied customers (be sure to ask permission first)... somebody who we can call on the phone and find out first hand what kind of experience they had. There's a trust threshold that has to be overcome here, because us stateside folks have no recourse for getting our money back should things not be on the up-and-up.

Nonetheless, I wish you luck... we could really use a pcb supplier with good quality and low prices.

Hi everybody,

A few days ago, I posted some information about
ceramic filters, and also mentioned that I have a few receiver designs,
product detector designs, etc. The response has been overwhelming to say
the least, so to be able to cover all of the worldwide requests for this
info, I need to somehow post the design, with schematics, board layouts, and
specs in binary form. Are binary postings ok on this newsgroup, and if not,
where can I post them for interested parties? I do want to mention that
this radio can be built for around 250 dollars or so, and the performance is
pretty similar to some of the solid state Collins equipment that I have
owned over the years. I am not looking for any compensation for this
effort; it is just my of saying thanks to all of the people in the world who
have helped me to get to where I am today. People like all of you!!!

Of course, the slope may be more immediately important than the actual
bandwidth.

If it was just a transmitter, one could use a relatively wide bandwidth
filter, indeed SSB isn't inherently narrow band, and keep the bandwidth
low by good audio filtering. Just as long as the filter is good enough
to chop off the unwanted sideband.

But since the filter is wanted for a transceiver, reception would be
affected by the relatively wide bandwidth. It probably wouldn't be
a consideration for limited use on the VHF bands, to get more SSB
activity going, but on HF it won't be so great. Again, one could
add good audio filtering on receive, but that will mess up the AGC
as in-channel signals affect the gain. Transmitting is a much more
controlled environment.

If you look in old articles about SSB rigs, there was a time when
LC filters were common for filtering. Using the IF coils out of
a Command Set (the one with the 85KHz IF) or some other pre-wound
coils, you could get good enough rejection if the IF was low enough.
That leads to problems with image of course.

I wonder how do-able it would be nowadays with toroids or pot-cores,
(or with terribly improved op-amps, how about an active filter around
50KHz or so?) and a conversion up to a frequency where a cheap and readily
available crystal filter would sit. I can put my hands on all
kinds of crystal filters in the HF range, but NBFM wide; all they
have to do is be narrow enough to get rid of the image from the
really low IF.

> from the companies as parts for those radio's.
>
> 73's John

This isn't a new idea. Years ago, you'd see articles where the author
suggested buying a replacement filter for a homebrew project, or any part
for that matter (I recall someone buying all the parts for an HW-101 VFO
for
their own use).

But about 1974 or '75, when I needed an SSB filter for something, I called
up the local Heathkit outlet to find the price of a crystal filter used
in their SB line. It was fairly expensive for the time, and no bargain
over buying a filter intended for construction, like a KVG.

And then you look at the price of add-on filters from the company
selling the rig, and either they are giving it a tremendous markup, or
we have to expect to pay an awful lot for good filters.

On the other hand, since some people do replace the original filter with
a better one, one source of filters might be finding people who have
upgraded, though that is hardly a source of a lot of filters.

It's a shame that one of the smaller companies selling relatively low cost
equipment or kits doesn't offer SSB (and even CW) filters on the side
to the homebrew market. Since they are buying in quantity, presumably
the price would be low. Sales to the homebrew market would hardly cut
into sales of their complete rigs, but it would be a source of filters
for those who want to build their own.

Or talk a company already selling parts, such as Dan's Small Parts, into
carrying some sort of relatively low cost filter.

Nice job! How much gain are you getting? Any idea of the frequency response?

With a reasonably good lab/data card for a PC, you could probably write a software curve tracer for a PC. I'm envisioning a D-to-A output to drive the base, a D-to-A output to supply the collector voltage, and an A-to-D stage to measure the collector current.

With the PC, you'd have the data in any form you wanted. You could have it printed out in tables, or you could use it to drive a plotting routine to display it on the screen (or, even on a printer).

Good luck with it, and please keep us informed. Thanks!

Dave

I know that it's possible to take a power transistor in a TO-3 package, and, with the careful use of a cutting tool (Dremel, hacksaw, etc.), to cut the top off of the package. This exposes the silicon wafer.

Once the silicon wafer is exposed, it is somewhat light sensitive (e.g., phototransistor).

Would it be possible to use the collector area of the wafer as the substrate for a point contact transistor? Or, would the oxide coating be too thick to puncture? What type of wires would be the best to use?

I remember that the original transistor was developed by accident while trying to make a low noise diode (I think the actual scenario was that a third electrode was added to a diode, and it was noticed that current flow between the electrodes were related, indicating an amplifying effect.).

What semiconductor materials would be good to make transistors from? Obviously, silicon and germanium will work. What about GaAs (Very poisonous!)? What about some of the other materials that used to be used for point contact diodes, such as galena?

What other types of solid state devices could be constructed? Could you fabricate your own FETs? What about UJTs (UniJunction Transistors)? SCRs and other four layer devices are probably out of the question. Could a MOSFET be fabricated?

Dave

If I remember correctly, the '96 Blazer was the same body style as the '89-'98 pickups. Working in a LMRS shop, I've punched and grommeted holes in the passenger side of the transmission hump (on the vertical riser) with some success (fairly quick, but you get "greased" by the undercarriage - so that's the "quick and dirty method"). On my own '91 Silverado; I didn't want to try that - wanted to keep spinning drill bits away from the 3-day old clutch slave cylinder. I found that the broadcast radio antenna coax went out through a HUGE THICK grommet just below the A/C evaporator box on the passenger side firewall. It took some time, but I managed to pull two #10 stranded lines out to the power buss next to the A/C dryer without cutting into the grommet; just "stuffed and cussed" it through with the antenna lead.

Before anybody starts yelling: 1.) Yes, stray RFI could be coupled from the new power leads onto the coax shield; if repeat IF you aren't using some kind of noise choke on the power. My thought's (and my Elmer's at the shop) was that strange noises on the stereo were preferable to erratic operation of the ABS system should go out the driver's side. 2.) That power buss is where the high-amp accessories and the alternator are connected to the battery. This almost guarantees the need for a noise filter on the radio lines; but is a much cleaner location to tie down the B+ leads. I've powered much gear from those points, 75W Micors, MASTR II - based IMTS rigs, solid state HF amps. My own gear has been powered from that point since July '91 with virtually no problems - can't say *zero trouble* - when one of the diodes gave up in my alternator, the chokes couldn't keep the ringing noise out of 6M TX with the brick on. Since it also didn't charge the battery properly, I just decided to replace the alternator. Problem solved.

I�ve seen a recipe for making a transistor out of ald coins and
electrolyte recently, but I�m not sure if it�s a joke. COULD work,
as you can make rectifiers from surprisingly primitive things!!

I�ll try when I get hold of a copy.

I also have some small article from I think the 60s on how to make a
transistor. If someone`s interested, tell me an appropriate place
where I can post the binary of the scan!

The suggestion to put them on a web page is perhaps the best answer,
as that would make them available for people to see in the future as
well. If you do want to post them, the standard procedure is something
like this:

1. Post the pictures to a miscellaneous binaries group (such as
alt.binaries.misc).

2. Announce on this newsgroup that you have posted the binaries on
alt.binaries.misc (or some other group if you use it), and say what
the subject line of the post is so that people can search for your
message in the thousands of messages on the group.

It's a bit of a bother, but it is the standard way of posting binaries
for groups that don't have dedicated binaries groups associated with
them.

It is not a good idea to post binaries to a discussion newsgroup.
I suggest you put the information on a web page. I agree with John Miles' recommendation of qsl.net. Their web and ftp servers are fast and reasonably reliable. My own web page is on qsl.net. I'm looking forward to seeing your design.

Source record: 60897

I just built the Ten Tec this last weekend. It was a lot of fun. I would suggest two things.

One, you can optionaly install a resonate circuit that will increase the sensitivity of the receiver, install it.

Two, the Ten Tec, like a lot of inexpensive kits, is not scaled and it is difficult for beginners (like me) to know where you're at in the band. If you have or can barrow a radio frequency meter like the one Radio Shack sells you can hold the antenna close to the receiver circuit to get an idea where you are tuned to.

Regens can be tricky but with some practice you should be able to pick up good signals. I've been able to pick up a lot of commercial stations from Japan to Germany. I have not yet, however, been able to pick up any ham signals.

Chris Dorn wrote:

In my post to Chris I noted to him that I am unable to pick up ham (CW or SSB) signals with my Ten Tec. I can pick up powerful commercial stations pretty well though so I know my receiver is working. I can tune through the ham band and pick up the "whistles" but I can't seem to resolve them.

Is it critical to have the radio grounded? It isn't but I could run a wire to a cold water pipe. I have not done so yet because I'd have to run the wire about 30 feet and then through a wall. Any ideas?

Thanks

Rick KC0GIX

Sorry for the belated response...I've been out of town.

The semiconductor is a chip of germanium stolen from a 1N34. Phosphor bronze electrodes, sharpened to extreme pinpoints, touch the face of the crystal with a spacing on the order of 0.002" The germanium is N-type, the P junction is formed by virtue of the electrode draining off free electrons. Conductivity is enhanced by a "forming" process wherein a small capacitor, charged from 45-90 volts, is dumped into the junction to cause extreme, localized heating. (something happens to the crystal structure, I'm led to believe.) To be honest, I don't fully understand the effects of the latter process yet, but the improvements are evident.

As to my motives, I recently published a book called "The Voice Of The Crystal". If you get QST, check out the May issue, page 41, for a review that I'm quite proud of. VOTC is a book about "from scratch" construction of radio components including coils, rotary variable capacitors, detectors, and several high-impedance "headphones" utilizing shoe-polish tins, transformer laminations, and even piezo cigarette lighter parts. The end result was simple, functional (crystal) radio equipment built from homebrew parts. Of course, a logical sequel to this involves amplification, through the use of homemade tubes and transistors, no?

I'd appreciate it *very much* if you'd forward a copy to me (just remove NOSPAM from my email address).

From what I've read, both copper oxides and sulfides exhibit semiconductor properties, and were the basis for a "transistor" patent filed by a guy named Lilienfeld as far back as the mid 1920's. Did the recipe specify pennies?

Very true. Alas, one must choose his battles.

Building my own curve tracer, either from pieces and parts, through the use of a computer and various
I/O cards, or even a little PIC-based device sounds fun and exciting. It's doable, and well within my
skillset on all accounts. The trouble is that my free time is *very* limited, and I can either spend
it on a tangent building a neat tool, or try to the obtain that tool through more direct means, and
maintain my focus on the actual project at hand.

I agree that ideally, the computer solution *would* be the best. You can collect data, slam the
numbers into a spreadsheet, and chart 'em at will.

As to specifications on my transistors, I have no formal specs, yet. I have probably set up a dozen or
more crystal/electrode sets in the three housings depicted, and destroyed them all exploring the
limits of junction voltages. Gain is impacted by factors like electrode spacing, electrode pressure,
electrode geometry, and factors relating to the crystal die itself.

Speaking of destroying transistors, preparing the electrodes is a painstaking process, only recently
made easier through the procurement of a microscope. (The electrodes you saw in the photomicrograph
were prepared using a simple jeweler's loupe. I may now be permanently cross-eyed!)

I know all about ladder filter design, and will do it if i find 455kHz ceramic resonators with suitably high Q and frequency tolerance.

The main reason for a 455kHz if is so that 'standard' 455kHz transformers can be used, and you can get more gain with less stages. I'm making the receiver compact/battery-portable, but without compromises.

Also, it'll have 10Hz step synthesized vfo, but not using a power-hungry/noisy dds.

3594. First receiver kit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-03 00:00:00 UTC
From: dorn@freenet.edmonton.ab.ca
Message-ID: <8eo71v$d2u$1@pulp.srv.ualberta.ca>
Source record: 60990

Hello,
I apologize if this topic has been covered to death. I am interested to build a receiver as a first kit effort. I am trying to decide between the Ten Tec 1253 or the Ramsey SR-1. I am leaning toward the Ramsey given that it is a superhet, and it is available at my local ham store. I don't mind that it is limited freq coverage. My goal is to spend modest funds to gain experience for a more advanced kit such as the TT 1254. Would the Ramsey be a decent choice? Are there any other options I could consider as a beginner? Thanks for your patience, and any advice appreciated.

Regards,
Chris VE6RDC

3595. HELP: Fiberglass mast source

Hi,

Thank you for reading this posting. I am currently looking for sources for fiberglass mast. The length does not have to be long. The size I am looking for is about 5 feet long (or longer). Strength might be a concern because I am using it in high wind area. If you know any place that I can find those, I'd like to share it with you and will appreciate your help. I am also looking for 500~1000pF 2000V variable capacitor.

Thanks for reading and 73,

Christopher VE3UVT

Forget the SR-1. I've built the SR-1 and the Ten Tec's. If you want an exercise in futility, build the SR-1. The design sucks, and you'll be lucky to receive much of anything. For example, the circuit they use for the audio amp (LM386) is just plain wrong.

If you want a real nice regen, that hears great, with a nice design, build the Ten Tec. If you are afraid about the complexity, you might consider the T-kit 1054, a 4 band SWL receiver. That being said, the Ten Tec 1253 is really not that hard to put together. Just follow the directions.

The folks at Ten Tec are really nice to deal with, very knowledgeable of their product, and the customer support is great. They've sent me replacement parts, no charge, when I offered to pay for them. They wouldn't hear of it. The 1254 is expensive, in my opinion, but someday I hope to be able to afford one. It's a real nice kit. Heck, if you've got the money now, get the 1254! I'll bet you could build it with no problem.

In any event, go for the Ten Tec, you won't be sorry.

HELLO,
I am a french OM (F4 AER)
as a am working on "the best design" for a cheap but
efficient SSB transceiver,As it is better to improve than to discover
things existings, I am looking for every schematics
concerning: SSB; IF amplifiers; ladder quartz filter for SSB,
using common components like NE612, MC1350P, PIC 16F84.
PA from 5 to 50 W using cheap transistors; SSB KITS descriptions,
synthetiseur PLL or DDS with PIC for exemple.

I am sending IRC's to cover the cost of your copy and postage
if you cant send me file or links

Many thanks,

Laurent

> resolve them.

I'm not quite sure what you mean by "powerful commercial stations", but if you mean BBC, etc., then yes, your receiver is working correctly. If you mean that you are only picking up your local AM station, then your receiver has a problem. I've built three of the Ten Tec 1253's and they all have excellent broadcast rejection.

> Is it critical to have the radio grounded?

"Critical"? No. Will it help? Yes. The more "critical" controls are the RF gain control, and the Regen control. If you hearing the "whistles", you should spend some time tweaking the regen and the RF gain controls. Basically, use only enough regen to bring in the station. Any change in RF gain, and to some extent, to volume control, will affect the reception capabilities of the radio. And I'm talking reeeeely small movements of the regen control.

The Ten Tec 1253 is a good, solid design, and really works well. Much better than my Star Roamer, Space Spanner, Heathkit, etc.

It's really worth reviewing the sections on using the controls, and spending some time operating your radio.

Hope this helps.

Just got the latest Nuts and Volts: Loaded with interesting surplus parts and stuff, but no Don Lancaster. Heard that he was being dropped for reader lack of interest. Same with Poptronics.

I may be one of the few around that like that kind of eclectic column, but we have lost a great resource. He apparently intends to continue on the WEB, but the loss of monthly publication is going to hurt a bunch.

I take RadioCom for the Tech Topics section (sorry, and G3SEK), 73 for Above and Beyond (and Wayne's ravings), Circuit Cellar just to see what is going on in that sector, CQ for the propagation and contesting, QST because it is there, QEX for the tech stuff, probably will drop Poptronics and Nuts and Volts (although I think I am a life subscriber to the latter) now that both have lost my main interest.

You might drop by N&V in the arena at Dayton and mention that you miss Don.

Peter: Thanks for the very inspirational postings! It reminds me a bit of the "homebrew tubes" articles that have appeared in QST over the years. I once cited the work of one intrepid Argentine ham who was making his own tubes -- my message was greated with much skepticisim. People just didn't believe it!

In case you don't know about the book, I suggest you take a look at "Crystal Fire" by Riordan and Hoddeson. Published in 1997, it does a very nice job of describing the development of the original point contact devices. It could have benefited from a few more diagrams, and the explanation of the theory behind these early transistors is kind of sketchy, but it is a very good book.

Good luck! 73 Bill N2CQR

Could it be that the electrical discharge of the capacitor is causing metal atoms to be diffused into the germanium/silicon? I'm aware of one technique where ion implantation is used for changing the type of the material. And, of course, there's the more normal diffusion. Does it make a difference in the direction of the discharge? It could also be that the thermal heating is disrupting the crystal structure, but, while this might enhance the conductivity, it would probably decrease the gain.

Dave

I've found a reference to the work of Lilienfeld:

http://ece-www.colorado.edu/~bart/book/mosintro.htm

And, here are a few more (Unfortunately, they're in German, and my
German is a bit rusty):

http://www.alien.de/degufo/rech16.htm
http://www.elektroniknet.de/fachthemen/bauelemente/artikel/ek9726b_1.htm

The first reference indicates that Lilienfeld's patent was number
US 1,745,175. Unfortunately, this patent is too old to appear on the
IBM patent web-server:

http://www.patents.ibm.com

But, from the web-sites I've referenced above, it appears that
Lilienfeld's work concentrated on field effect transistors (FET) and not
bipolar junction transistors (BJT).

Does anyone have access to the actual patent document?

Dave

P.S. Standard Disclaimer: I work for them, but I don't speak for them.

I think most of us have heard about Copper-Oxide rectifiers. Plus, who could ever forget about Selenium rectifiers, but I'm not sure how much of a semiconductor Selenium is (plus, I think it's rather posionous, at least, in some forms).

There were also electrolytic rectifiers used back in the distant past, but I'm not sure if these could be made into a transistor. Of course, there is some interesting work going on now involving liquid transistors, with the active material being a hydrocarbon (I'm serious!). The liquid transistors could be painted onto a substrate. I think one area of interest is for driving liquid crystal displays.

I'd be interested in seeing both the articles mentioned above.

Dave

Thermal effects will make measurements a bit distorted, unless you do
pulsed measurements.

According to the scant information I've found, the answer is yes on both accounts. Both the thermal
disruption of the crystal, and to a lesser extent, ion migration (of the phosphorus) serves to improve
the junction.

Strangely, the one document I have that that talks about "forming" describes dumping the cap into the
junction in the reverse direction.

Another point well taken. I've observed considerable drift (due to thermal effects) while making my
measurments. To minimize this effect I now do them with pushbuttons, as a muffin fan blows over the
junction.

Have a look at my new four band SSB transceiver. The design is
very simple. I use a 7.8MHz crystal filter, from a scrap CB.
All transmitter stages are run in class A, for improved linearity.

I had always assumed that the Germanium transistors, since they can't be
passivated, would never last for more than a matter of hours or days,
because of contamination from the air. Maybe the point contact isn't
that critical.

It would be nice to have a Linux version and a Mac version. Perhaps we
could persuade Reg to put the source code on his web site?

The following C program is based on the well known formula:
(n^2 * r^2) / (9*r + 10*l)

To compile under Linux:
gcc -lm whatever-you-call-it.c

#include <stdio.h>
#include <math.h>

int main(void)

{
float N,l,r,result;

printf("\n\nCoil length in inches ? ");
scanf("%f",&l);

printf("\n\nCoil radius in inches ? ");
scanf("%f",&r);

printf("\n\nNumber of turns ? ");
scanf("%f",&N);

result = ((N*N)*(r*r))/((9 * r) + (10 * l));

printf("\n\n%f MicroHenries\n\n\n",result);

}

Hi,
Pete Friedrichs wondered:

>From what I've read, both copper oxides and sulfides exhibit semiconductor properties,
>and were the basis for a "transistor" patent filed by a guy named Lilienfeld as far
>back as the mid 1920's. Did the recipe specify pennies?

Lilienfeld's work gets rediscovered every few years. A good
reference is Physics Today, February 1964, pp.24-26 and May 1964,
pp.60-62. There is no evidence that his devices worked.

Someone mentioned pulse operation of the curve tracer to avoid
thermal effects. The commercial Tektronix tracers will do this, but
I'm sure are too large an investment for a one-time project.

Hello,
you can find a schematic on the February 2000 issue of Elektor
Electronics for the RX part. I haven't test it, but its simple enough to
build.
Cheers,
Nuno Sucena

3625. New antenna program MAGLOOP4

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-04 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <8eqbt1$2ot$1@plutonium.btinternet.com>
Source record: 60930

Program MAGLOOP4.exe is an improved and updated version of RJELOOP1.
It analyses performance and assists with design of magnetic loop
antennas of various regular shapes from triangular to circular.

The program now has facilities to sweep input parameters of loop
perimeter, conductor diameter, height above ground, soil resistivity
and operating frequency over a wide range of values while observing
computed performance data. Performance includes percentages of
transmitter output power dissipated in the ground under the antenna
and that lost in the conductor RF skin resistance.

The behaviour of a loop at low heights, including the de-tuning effect
of close proximity to other materials, are modelled with greater
accuracy than hitherto. Obseve how the computed tuning capacitance and
loss changes as height above low-resistance ground or sea water
decreases to 10 mm (0.4 inches).

An improvement in the accuracy of predicting radiating efficiency as
the loop perimeter nears 1/2-wavelength may be of interest but is not
of great importance. Efficiency is very high anyway and the
space-saving virtues of magloops are diminished with the large
relative loop diameters.

The not-very-useful values of loop inductance, radiation resistance
and conductor resistance are no longer displayed. The all-important
values of tuning capacitance and peak volts across the capacitor have,
of course, been retained.

A inovation of the program is the very practical illustration of
magloop performance by predicting S-meter readings of receivers at
radio path distances of 800 km (500 miles, 1 hop in darkness) and 8000
km (5000 miles, 3 hops in sunlight), via the F-layer at frequencies
not too different from MUF, for any given transmitter power output.

Transmitter power into a magloop is eventually limited by the peak
working voltage of an expensive, relatively large value, variable
tuning capacitor. If the program predicted the minimum spacing
between the plates of such a capacitor it would probably lead to
argument. Has anyone any ideas on that subject ? Spacing versus
volts and frequency ? A formula ?

Download program MAGLOOP4 from my website in a few seconds. Not zipped
up. Run immediately and entertain yourself.

Regards to all, Reg, G4FGQ

3628. Knight Rider Scanner

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-05 00:00:00 UTC
From: weyoun7@aol.com
Message-ID: <20000505125203.05659.00001593@ng-cp1.aol.com>
Source record: 60846

Can someone suggest to me a circuit that can produce the effect as seen on the Knight Rider Scanner? I'm wanting to do with this with LEDs for right now.

For those that don't know the effect is a row of light (say 8 to 10) and the lights light up and go back and forth, but it's not a LED follower. This looks more like a game of ping pong, so the LEDs light and travle to one end then return. The LEDs also sort of trail one another in a slow fade, I figure I can reproduce that effect with some caps.

Thanks for any suggestions or hints,
-Justin R.

Maybe I can help a little here. I have built a repro 1911 type RX using silicon, electrolytic and a home brew Marconi type magnetic detector. The only problem with the "maggie",
by the way is the difficulty of getting really fine soft iron wire for the loop. It does work quite well as a detector however. However Peter Jensen's suggestion of using recording tape instead of soft iron didn't work in my setup.
As to spark Tx gear, I have built low power spark TX's using original fixed gaps, rotary gaps (using 400 Hz AC) and have attempted a "Quenched gap" a la Telefunken.

This last is however very hard to scale and the shaping and machining of the spark gap discs is both difficult and subtle.
An old friend of mine built a very sucessful early Marconi rig using a coherer which worked over hundreds of feet. However he unfortunately died last year.

So basically my experience is basically with later pre WW1 Marconi gear. On that basis I would say that for a small TX thr rotary gap is the easiest to get going. By all means contact me if I can help.

From: dr.dongle@juno.com
Message-ID: <8etemh$k4o$1@nnrp1.deja.com>
Source record: 60934

I saw an artical from the UK a while back on modifying TVRO LNB's to convert them to transmitters. I have several defunkt Primestar dishes and recently opened up one of the LNB's which was very similar to the unit in the artical. Has any one explored this?
It appears that the two "pill" tranisistors in each section (one Horizontal and one vertical) could be moved 180 degrees and the various filter ckts modifyed as in the artical.

From: Joe Leikhim <jleikhim@nettally.com>
Message-ID: <39124C5A.F634F04E@nettally.com>
Source record: 60937

I am looking for a modern stepper relay.

Specifically what I am looking to do is switch 4 to 8 legs of a Beverage array remotely with a simple pair of wires. I only wish to pulse the relay, not have to apply a continuous voltage.

I have heard of a relay called "Rotomite" but cannot find any info on one. Looking for a source of same or similar.

Thanks

3640. Dual Voltage Power Supply Metering?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-05 00:00:00 UTC
From: k7on@earthlink.net
Message-ID: <MPG.137c80bf8279cc3f989686@news.earthlink.net>
Source record: 60939

I recently finished a small power supply for experimenting
with various circuits (a "bench" supply).

It has dual voltages, individually controllable (1.2 to 21.5 and
-1.2 to -21.5) - as well as +/-12, +/-5, and +/-23 unregulated.
Not a high current supply, just handy - I hope.

Anyway, I left sufficient (I hope) space on the front panel
for metering of the two variable voltages.

I am now looking for suggestions for (inexpensively) adding
metering to this supply, for example 3-digit digital readout
XX.X or -XX.X etc of voltage (or possibly current also).

Anyone know of (cheap, simple) 3 digit voltage meters that
might be added to this project?

Thanks, Brian

Source record: 60852

Hey Justin,

Try your favorite 8-bit processor chip (Atmel or PIC, for example) directly driving the LEDs. If you get ambitious enough, you could even do the fade in software by driving the LEDs with a software-controlled variable duty cycle square wave. Whole circuit would be 1 chip, 1 resistor and the LEDs (plus a bunch of software, of course).

If you're not into a software implementation, then try a couple of 74LS194A 4-bit bidirectional shift registers. You'll have to add a few glue logic chips to do the initial load at power-up and to detect when the direction needs to change, as well as a clock. I'm guessing that'd take a couple of flip flops and a 555. The parts count would definitely be higher, as would the size of the board and the assembly time, but it'd be a purely hardware project.

And if you really want to be low tech, try an electric motor pushing a wiper contact a la windshield wipers :-)

I've not ben following this thread, so pardon me if I repeat something that's already been suggested, but have you considered the TenTec transverters?

I have the six meter to 20 meter transverter and I am very pleased. With only 8 watts to a rotatable dipole I have worked from EM75 (near Chattanooga, TN) into New England, FL, Mexico and CO.

3649. Homebrew receiver models... which one??

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-06 00:00:00 UTC
From: Linda Wolford <Miss-Linda@email.msn.com>
Message-ID: <#8U1z#2t$GA.306@cpmsnbbsa04>
Source record: 60854

I am interested in building my first homebrew reciever, not sure which design I want. Here's how I see it:

I want it single-signal (superhet) design

I need it to have, what Doug Demaw in his 'His Emminence (1976+/-) Receiver' design described as DYNAMIC RANGE. What seems so suprising is how the older design utilizing DIODE mixers appear to have this down better than the new fangled NE602 craze.

I want this receiver to separate nearby signals well FROM THE ONSET (the mixer and IF stages, etc), not just one that settles for second best in the front end and depend on an audio filter to make up for the poor front end and 'oversimplification' by leaving out additional mixer stages. I don't care how complex, or if it ends up having 200 knobs for selectivity, etc.

Also, any ideas on making the tuning capacitor work mechanically SUPER-SLOW.... I want a rig set up to be wide and slow, like taking a walk across some desolate E-W highway by foot, with towns thirty-plus miles in between one another! I think you get the idea!

Any sites where I could find schematics for these would be appreciated (or we could do a snail-mail, whatever)

Thanks Brad N4trc Miss-Linda@msn.com

3650. Re: Cheap 455kHz SSB filters?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-06 00:00:00 UTC

Source record: 60855
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.components

Altho the specs look promising, all murata ceramic filters
I've tried suffer from poor skirt rejection. Fooling with
termination doesn't seem to help much.

A cheap solution is using the small ones in series.

Example. Using the simple 5 pin 2 element SFD455 in series
makes a pretty good filter if the element coupling caps are
around 10pF. Two in series is better than some of the multi
element filters and four in series gets quite good.
More gets proportionally better.

Since this is a multiplication process, the passband response
[0db] stays the same but the skirt selectivity improves remarkably.
If a skirt frequency is down 10db for one then it will be down
20db for two and 40db down for four in series.

Downside is insertion loss which also multiplies but this may
be compensated with a simple bipolar gain stage at the end
to recover signal level.

Surely, nobody is promoting the 80's NE602 in the signal path of in a
high-performance design. We do see it still in modern "simple"
receivers, or QRP low-current receivers.

>I want this receiver to separate nearby signals well FROM THE ONSET (the
>mixer and IF stages, etc), not just one that settles for second best in the
>front end and depend on an audio filter to make up for the poor front end
>and 'oversimplification' by leaving out additional mixer stages. I don't
>care how complex, or if it ends up having 200 knobs for selectivity, etc.

The "old style" dual-conversion 70's receiver with a tuned antenna LC,
a tuned RF LC, and a tuned osc LC certainly had some advantages in
cutting down out-of-passband signals. For single bands having all
those coils is not much of a problem, but we get a lot more complexity
in a general communications receiver. In that case maybe the best bet
is to find a broken-down tube model and take the tuning system.

Selectivity is available in ceramic filters of modest price, or
do-it-yourself crystal filters. Crystals are quite available.

Modern frequency accuracy and stability are crystal controlled, with
the 80's phase-locked loop (PLL) and 90's direct digital synthesis
(DDS) currently fighting it out.

>Also, any ideas on making the tuning capacitor work mechanically
>SUPER-SLOW.... I want a rig set up to be wide and slow, like taking a walk
>across some desolate E-W highway by foot, with towns thirty-plus miles in
>between one another! I think you get the idea!

There are various older options: 1) Get a super-slow mechanical
reduction drive; 2) Use a large bandset and a small bandspread (dual
or triple) in parallel; 3) Switch-select fixed caps (bandset) and use
the tuning cap as a bandspread. One could use varicaps with 10-turn

pots and even bandset/bandspread, but using varicaps anywhere there may be a strong signal can be tricky if we want high performance.

Nowadays, osc frequency is generally digitally-controlled, and that can be as slow as we want. After that, one option is to use no-tune bandpass filters for ant and RF. Another option is to go straight to broadband amplification, but then we have intermodulation issues which we might generally avoid by tuning out most strong signals. Really modern stuff does direct conversion with quadrature mixing and re-combines the results to select one sideband direction.

>Any sites where I could find schematics for these would be appreciated (or >we could do a snail-mail, whatever)

http://www.pan-tex.net/usr/r/receivers/

plus the 2000 ARRL Handbook.

My opinion.

Brad: Sounds pretty ambitious for a first time receiver builder. I'd
suggest starting out with something simple. But not too simple.
Definitely go for the superhet with single signal reception. I'm a
big fan of Doug DeMaw's Barebones Superhet. June 82 QST. Works
great! I added an RF stage. Lots of fun.

FB that you are planning on building a receiver. There are very few
RX builders out there. I'd say sitck with it, but I would advise
starting out with something a bit less complex than what you outlined.

Check out my web site for more info on the barebones receiver.

A couple of thoughts:

Good old LM-10 Frequency meters have a very high ratio reduction gear driving a capacitor in them. Generaly they are available for $10 or so at Hamfests and on eBay. You can make a VERY slow tuning VFO with one of them. When I build a reciever based on one it cured me of the need to have a slow tuning radio (50 turns to go 10 KHz is just to slow.....)

Mini Circuits distributors will sell small quanities of some pretty high level double balanced mixers so that part of the equation should not be a problem.

High frequency (well above 455 KHz) crystal filters are a common item on eBay and you can generaly find them at most larger Hamfests. If you are designing from scratch the center frequency does not matter as much to you so you can buy the ones at odd frequencied (ie the cheap ones ...)

I'd recomend starting out with a single band single application reciever. That way it is a no compromise design AND you can finish it without spending large bundles of money. There is also a lot to be said for completing projects before they are eligable to vote ... need to learn that one myself :)

One example would be a 20 Meter reciever for PSK-31. It should be usefull when you are done and you can build one that will crush anything you can buy.

Just my two cents worth.

Building a first receiver is tough, but building a high performance one is nigh impossible for an inexperienced ham. A simple receiver successfully built will give you something with which to compare the later efforts. A couple of recommendations: Build something like the KK7B DC receiver, for 40 meters. His receiver, although not perfect, is light_years ahead of everything else. When you get tired of it, you can use it as the detector/audio portion of a superhet. The kits come in several flavors, and Kanga (Bill Kelsey) had them a few years ago. Why 40 meters? Well, 40 is where you can audibly test a receiver for robustness at any time after dark via the foreign broadcasters!!! The other bands are tame compared to 40 (except for field day or contest weekends). John Siebold has a site with tons of info on everything about the KK7B receiver. John has lurked around here at one time or another. Another recommended site is http://www.ac6v.com Rod has an excellent site, and it'll take months to run down all the good stuff.
While you are building, document it well. You may someday have material for a web page or a magazine article. Good luck on the construction and keep us on the NG posted.

Official announcement

All the hardware goodies related to the JRC NRD-515, were you already
may have heard off are now made public to everyone.
That is all sorts of modifications of the JRC memory unit (515 and 518)
and some for the NRD-515 receiver itself. Photographs available!
Also lots of info about the active aerial project and some info about a
huge (150 sq. meters) coaxial loop. Some words were spend on that loop
in the Dutch Electron monthly and that publication was referenced again
in the British Radcom. Now more first-hand info available!

Disclaimer remark: almost every modification demands a thorough
knowledge of the radio electronics and good soldering skill, or else
could certainly ruin your equipment. Total ruins are NOT our
responsibility.

Be amazed and see for yourself, go to:
http://web.inter.nl.net/hcc/Shortwave
click on index icon and go to the 515 subdivision

Thanks for the comments, folks.

I have the MFJ qrp rigs, based on the NE602... The sensitivity will pass, but the stability and especially the adjacent frequency rejection has much to be desired... I don't need luxuries such as digital displays, for it will be intended for portable work.

My understanding is that, by adding additional stages of mixing, then filtering, then amplifying, mixing then filtering then amplifying, mixing then filtering then amplifying, I can get better performance... And yes, forty is my first band of concern, but the ability to add front-end converters for twenty (at least) would be nice, too!

I have certification in electronics, so I can read schematics, and align and test, too (have a dip meter, a freq counter and VOM, too!). If I do one of these 'simple' jobs, I'll most likely get the same performance as these MFJ QRP CW rigs.

But maybe a modification to this MFJ rig could be suggested... additional stages of the same calibre? Better IF filtering? Where to place them in the existing circuit? I also noted that this rig appears to do a poor job of shielding the LO from the rest (unless they figure that the NE602 does all of this, somehow)... In most receivers that I have 'broken into', I see the tuning capacitor (at least) in its own shielded enclosure... maybe they figure that one single mixer stage doesn't produce enough to worry with on that point, but once again, look what it gives up in the process!

Brad: If your standard of comparison is the MFJ rig, then about anything
you can solder up will outperform it. Don't equate "simple" with low
performance.
A simple receiver CAN have a low dynamic range, poor selectivity,frequency
instability, and a list of other complaints. But it is a certainty that if
you design and build a complex receiver (unless you are DJ2LR) that it
will perform worse in some areas than a basic receiver, and perhaps worse in
all of them.
Key to homebrew receiver design is to specify your requirements EXACTLY,
and then borrow just enough circuits from the available literature to meet
those requirements. One additional circuit lowers the performance!!! You
really threw a difficult task in by calling for portable operation. Portable
means wide temperature excursions and low power consumption, perhaps from
batteries or solar panels.
I recommended the KK7B series of kits and I'll again make that
suggestion: there are 3 different types (or styles if you prefer) of
receiver circuitry, plus a phasing exciter and the T/R board, so that a
complete QRP multi-mode rig can be assembled from one source. Rick's
circuitry was designed for high dynamic range, portable operation, and low
power consumption. The accompanying articles do an excellent job of
explaining the why's of receiver design.
A local op uses his JST-245 transceiver as the vfo for a KK7B receiver
on 40 meter packet. Works outstandingly well!!!
One of the other posts on this thread mentioned uncompleted projects
also: it is EASY to get started, difficult to finish. My receiver building
goes back to the late '50's, and I have more uncompleted projects than I
have completed ones. But there is no better feeling in this life than to
work a contact on a piece of gear you've built.

The best source of receiver information in one book is Hayward and Demaw's "Solid State Design for the Amateur". Published about 20 years ago, it's still the most practical guide around. Another must-read is Roy W7EL Lewallen's QST articles on QRP transceivers.
There is a wealth of info on receiver design out there, it's just not really simple to find and digest. While today's transceivers perform well, homebrew stuff can beat 'em in lots of areas when designed and built correctly.
Let's keep the receiver thread going!!!

Whitney,

Since they show data on the data sheet up to 1 watt input I'd guess
that you are safe up to that point. Beyond a watt who knows .... I'd
bet at least 5 cents that you would be ok to 2 watts :)

For sale, brand new, steatite antenna insulator. Can be used for that monster antenna or as a conversation piece or paperweight. You don't see these very often! White color, about 7.25 inches long, 1 and 5/8 wide, and 1 1/8 thick. Hole in each end about 3/8 inch diameter. Will sell for $3 and whatever the shipping costs will be. I have more than one if you'd like some as gifts. You won't flash this one over no matter how much power you run!

>
> My understanding is that, by adding additional stages of mixing, then
>filtering, then amplifying, mixing then filtering then amplifying, mixing
>then filtering then amplifying, I can get better performance...

Your understanding is wrong. You want to use as few mixing stages
as practical to meet your image rejection and selectivity requirements.
More stages just produce more spurious products, more reciprocal
mixing problems due to phase noise from multiple LOs, birdies, etc.

With the advent of good high frequency crystal filters, a highest
performance superhetrodyne receiver will be single conversion
for any single HF ham band. Adding more conversion stages will
just degrade performance.

But if you want to cover all of HF, you'll need at least 2 conversions,
the first at a relatively high IF to get image rejection, and the second
at a lower IF to get sufficient skirt selectivity. If in addition you want
continuous coverage tuning, then you may need to go to 3 conversions,
with the first conversion being an up conversion to well above HF.
Perhaps you might even go to 4 conversions if you want passband
tuning. But those extra conversions cost you in terms of the ultimate
performance of the receiver on any single band.

Now the components of a single conversion receiver have to be chosen
appropriately, and the circuitry has to be designed and executed properly,
in order to realize the highest levels of performance. You can build a truely
awful single conversion receiver nearly as easily as you can build a truely
awful multiple conversion receiver. But if you use best effort in the design
of a single band single conversion receiver, it will be better than you can
achieve with best effort for a multiple conversion receiver.

A direct conversion *phasing* receiver, can actually be better than a
superhetrodyne if it is implemented properly. The KK7B design, modified
to use a DSP, as published in QST, and used with a preselector, will
produce *excellent* results. The biggest issue is lack of good AGC,
which means you may have to manually ride a front end attenuator in
some cases to maintain an adequate dynamic range. That can be
resolved with some small design changes.

You have to hear one of these setups to believe it. That something so
tiny and apparently simple can sound so good will open your eyes.
(It is simple only in terms of low parts count, however, the design is
very sophisticated in terms of being optimized for its very well defined
task.)

What would be awesome in my mind is to just make a simple audio oscillator with the homemade transistor, and some handmade coils and parts. Maybe hand wind a transformer. The claim that you had an amplifier that used a homemade transistor just by itself is a claim that almost no one else has made or can make. Even better would be to use some homemade batteries.

No, it's the impedance. The impedance is the square of the turns, so if
you take half the turns, you get a quarter of the impedance, looks like
2.5k per side for this setup. That sounds about right for an average
tube rig. You don't want to go too low because you won't get enough
modulation. Using the transformer like this balances the current in the
winding, so it doesn't saturate.

According to the Mitsubishi databook I have, at 13.5 volts at 175MHz, they up to 1.0 watt input (9.0 watts out) on an Output power vs. input power graph.

Another graph of Output power vs. collector supply voltage show trends for various inputs up to 0.8 watt at up to 16.0 volts collector supply (and at these ratings at 175MHz, they are showing about 9.4 watts out).

And the electrical characteristics chart (at 25C) says for 13.5 volts at 175MHz, with 0.6 watts in you will get a minimum of 6 watts out (7 watts typcially).

Under absolute maximum ratings, there is no such specification of maximum input power. Maximum collector current I believe is 1.2 Amps (though my data book seems to be missing the decimal point and reads 12 which it definitely is not since the 2SC1972, the higher power version is only 3.5 amperes). Maximum power dissipation at 25C case temperature is 12.5 watts.

I just finished a DSW20 10 days ago. Easy for a first time construction kit to someone without a technical background. Instructions were very complete and the support by Dave Benson is excellent.

I live near Chicago and am happy with QSOs from British Columbia to Maine to Utah to North Carolina. 18 Q's in the QRPTTF and 8 in the Spartan sprints. Most reports were 55N or better, including non-contest Qs, which are usually 55N no matter what.

The features I like is that it always starts at 14.060 (QRP calling freq), the digital freq readout (that really spoils me) and the internal keyer.

There usually is a few week waiting list for the DSW series, so that should also tell you something.

True, using multiple IF's allow gain distribution, but that also results in relatively high signals into the second mixer. Presuming a high first IF, with a relatively broad filter, that increases the probability of intermod overload in the mixer.

Careful construction and shielding allows a lot of gain at one frequency. So, a single conversion is the best approach for good performance with "common" analog components.

And, for the purposes of QRP, I'm assuming CW, although SSB is certainly possible.

Personally, I like a superhet over direct conversion, although the KK7B design is very good. I just like the AGC and not having to do the quadrature RF and so on....

==========

If I remember the earlier comments correctly, 40 meters was the primary band. There's a design for a very good strong dynamic range with excellent selectivity 40 meter CW unit in the ARRL "QRP POWER".(originally from the march 1993 QEX).

This uses a diode DBM, 12 MHz crystals in the filters, with an input filter and an output filter for the IF to help the selectivity and to scrape off the wideband noise of the IF amplifiers.

I'd certainly recommend this a design to study and, perhaps, duplicate. It's about as good of a CW design as I've seen for a straight forward homebrewer 40 meter job.

Oh yeah, he chose 12 MHz, because it made the crystal filters work out to be 50 ohm IN/OUT. Cute.... And a good idea.

==========

I wrote a spur analysis program and found that 5 MHz crystals along with a 2.1 MHz VFO work for 7 MHz with few spurs, although the filter impedances are something like 250 - 300 ohms (depending on this and that).

Still, making a stable 2.1 MHz VCO is fairly simple, and 5 MHz timebase crystals are cheap.

Jim

No. They are all meant to be used as wrap around on threads on
plumbing/water pipes.

By the way, nurseries and gardening supply places sell rolls of1 inch wide
copper tape
with adhesive on one side. They are meant to be used as barriers against
snails but can probably find use in a ham shack. I bought a 15 foot roll for
5 bucks. I separated some from the adhesive strip to measure it and it is 5
mils thick. It is very easy to separate it from the adhesive strip - peels
right off.

Pete,

If you want to go way out and don't mind the software there are some pretty good 14 bit high speed ADC's out there that will digitize everything below 30 MHz all in one pass ....

But gain distribution doesn't have to denote putting the filter later
in the chain.

There was a receiver in QST for May 1965, the "MIser's Dream" by Byron
Goodman, that used double conversion but the selectivity was all
in the first IF. The SSB filter was right after the 7360 mixer, and
then the CW filter was after a stage of amplification. He found he
had to put the product detector and BFO on a different frequency, because
otherwise the BFO was getting back into the IF and causing problems.
At first glance it looks silly, having a whole extra conversion (and
the tubes to do it) just to follow it with a simple diode product detector,
but if it makes the rest of the design simpler, then it is worth
examining.

One could put a really good filter after the first mixer, as long
as one can get it or is willing to pay the money (in the case of
a "roofing filter" somewhere above 30MHz), and as long as
the receiver is only going to receiver SSB or narrower signals. Once
you get into multimode and AM and even FM, the first filter has
to be much wider, and that will make the rest more difficult.

And remember, the desire for full coverage has driven the need for
up conversion. If someone is building a ham band only receiver, or
willing to have some gaps in general coverage, they can put the
IF in the HF range where there are good SSB-width filters, or where
ladder filters can be built. I'm not sure what that has to do

with gain distribution, but it does mean one can put a good filter right after the first mixer, and then convert to another frequency for other reasons.

It is silly to judge a receiver by how many conversions it has, like I often do see people do in rec.radio.shortwave Too many seem to think that dual conversion is better than single, and that triple is even better. The overall design is far more important. And no matter what you change, something else will come into effect.

Double conversion does add another overload-sensitive mixer, and another oscillator to worry about creating spurs, but in some cases it may make the rest of the design simpler. You have to look at everything, not just one stage.

I also gather that in cases where really good skirt selectivity is desired, a limiting factor is isolation around the filter. Adding a conversion and putting another filter at the second IF builds up the skirt, whereas working it all on one IF frequency requires an awful lof of work to isolate the stages and get an increase in skirt selectivity after a certain point.

These are the values I had to find when I built my homebrewed horizontal 1/2 wl square loop antenna for 6m!! I needed the feed point Z value (combined radiation resistance
and conductor resistance) to design the matching network so I used a MFJ 269 antenna analyzer to measure the value (12 to 14 ohms at resonance). The matching network I used was two paralleled 1/4 wl sections of RG-58 cable and the "capacitor" was totally unnecessary. I get a match of 1.1 to 1.2 at the center frequency of 50.200MHz and the 1.5:1 SWR bandwidth is around 450KHz.

You may not find the above of much use, but don't assume that others will not! If I did not have the little gem of an antenna analyzer I would have had to find some place/program to calculate the value.

Hi there,

Does anyone know of a crystal manufacturer in the USA willing to cut
crystals in only ones or twos below 1 MHz?

I require one or two HC6 or HC48 990 kHz fundamental parallel
resonance 30 pF load capacity.

UK manufactures are outrageously expensive at these frequencies for
one-offs!

Thanks,

Ian

Hi gang,

I just finished building the QK63 one chip AMBC radio from QKits

http://www.qkits.com/serv/qkits/diy/pages/QK63.asp

It is a TRF style rx that uses an MK484 IC which they say is a Japanese copy of the original ZN414. Works pretty good. The specs on the MK484 say it goes up to 3MHz, so it could make up an IF for a converter for the band of choice.

This might also be a good kit for some first time builders. The pads on the pcb are quite small, but there are few components so it should not present too much trouble for the newbie.

I have no connection to QKits. Just thought you folks might like a report.

Source record: 60802

Magloop4 program applies only to magloops where the feedline is not attached directly to the main loop.

Loop inductance is not displayed because it is only of use in calculating the value of the tuning capacitor - but the program already displays the tuning capacitance.

Radiation resistance, conductor resistance and ground loss resistance are not displayed because they are used to calculate radiating efficiency - a parameter whuch the program DOES display anyway.

The program computes and displays the diameter of the coupling loop required to transform the main loop resistances to a 50 ohms feedline. (Or to some other standard value if required.). Again, the loop builder needs no knowledge of radiation and othe resistances. He follows the program's computed dimension and uses his impedance meter just to check the 50-ohm feedpoint input resistance.

To predict feedpoint impedances of other types of loop use Eznec and similar programs. Yes, the relatively new antenna analysers really are 'little gems'.

Regards, Reg.

International Crystal (http://www.icmfg.com) and JAN Crystals will both
do it.

Problem is price -- about $75 US for crystals under 1 Mhz from IC. JAN
is a few dollars less, but still about $70.00.

Give Reg his due - the notes in SOLNOID2 say that the program is based on Nagaoka's work, so that pretty much ties down what the algorithms are.

There was a Tech Correspondence piece in QST for April 1992 (correction in June) which pointed out that this whole single layer solenoid problem was thoroughly worked out by about 1915! The formulas are as long as your arm, with elliptic integrals and suchlike, so they stayed in the textbooks until PCs made them practical.

As for the Linux/Mac versions, it's simply a matter of coding up the published formulas. All the references are in QST, along with simplified formulas.

A lot of these issues are really non-issues. If you want
dynamic range, use a high dynamic range front end with
proper mixer termination - a diode ring or a DMOS FET
mixer will do the job nicely. COnsider a switching
mixer built around a 74HC4066 or FST3125.

Selectivity: superheterodyne has nothing to do with
single-signal reception. That is a function of really
sharp filtering, or an image reject mixer.

As others have mentioned, the series of articles
published by KK7B in QST (and reprinted in QRP Power)
show what is possible. With modern components it
doesn't matter too much what order detection,
selection and amplification happen in...

Source record: 60809

I suppose the "code input" will modulate the input impedance of the transistor, and especially the input capacitance, causing a slight frequency shift because of the changing load on the resonator. There is presumably some amplitude change as well, though I would expect not very much; and your comment about a PLL receiver indicates that you are detecting the frequency modulation, not any incidental amplitude modulation. And I suppose the resonator must be a SAW (surface acoustic wave) resonator: 400MHz is a bit high for a standard quartz crystal unit. The transistor, of course, is acting as an oscillator/amplifier, its collector output coupled to the antenna.

Cheers,
Tom

I agree with your comments. I was directing my message towards the original request for a monoband 40 meter that was reasonable for a homebrewer to tackle.

For general coverage, upconversion has a LOT to be said for it..... And, there are reasonable filters at those frequencies.

However, I would not recommend that sort of complexity for a first project.

3702. Question: Cascading bi-stable latching relays??

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-08 00:00:00 UTC
From: Joe Leikhim <jleikhim@nettally.com>
Message-ID: <39177A51.BC5EB312@nettally.com>
Source record: 60811
Cross-posted to: sci.electronics.components,rec.radio.amateur.homebrew,rec.radio.amateur.antenna,sci.electronics.equipment

I have been trying to come up with a way to cascade three or four
bi-stable latching relays (DPDT) so that I can sequentially close one of
four circuits on each pulse.

The application is one of switching longwire antenna segments, (See my
inquiry about stepping relays on the sci.electronics.components NG for
more info):

1st pulse = East
2nd pulse = South
3rd pulse = West
4th pulse = North
and so on.

Get the idea?

Want to avoid active circuits requiring continuous power.

Reg, correct me if I am wrong. I had thought that a magloop antenna was nothing more than a antenna where the element is "electrically short" for the intended operating frequency. The tuning loop, and the capacitor form a simple 'L-Match" to transform the low loop impedance to the normal 50 ohms.

I had looked at the M-Squared "Ho-Loop" design and it appears to be a magloop type of antenna. From what I can see M-Squared "cut" the antenna length to give the required capacitive reactance without using a discrete capacitor. The matching loop is very cleverly designed as a shorted stub at the feed point, with the shorting bar (at the end of the stub), used to mount the antenna to the mast while providing a DC path to ground. Is this a correct analysis of the design? The reason why I am asking is for my own information. The M-Squared design was one that I had looked at as a model for a homebrewed 6m loop antenna design I was working on.

>
> My understanding is that, by adding additional stages of mixing, then
> filtering, then amplifying, mixing then filtering then amplifying, mixing
> then filtering then amplifying, I can get better performance

Not necessarily. Good performance is quite possible with direct conversion, provided one is willing to put up with the audio image. I'm not sure if the MFJ is direct conversion or superhet, but I've had excellent results with the NN1G SW40+ , which is a superhet with NE602 and on-board VFO. Stability is OK and the crystal filter is selective enough.

If you wanted to experiment with direct conversion, I would suggest using a different mixer. I have built a DC RX that includes the following:

RF Amp: 2N4427
Mixer: 74HC4066
LO/Buffer: 74HC04 with 3.58 MHz ceramic resonator
Diplexer: As per KK7B
AF preamp: 3xBC548/2N2222 - as per KK7B
LPF: as per KK7B
AF: 4007 biased to linear

Performance is extremely good. The set covers 40 and 20 by switching in appropriate band pass filters before the mixer. Harmonic mixing is used - hence no VFO switching. The only problem is hum - it exists even when the set is
powered by an external battery. The box is metal and fully enclosed. \main strengths are dynamic range and audio fidelity.

Mr. Coffman, you are correct in your assessment that it would be better to keep the number of conversions "down" but that a double conversion receiver is pretty much neccessary for a wide coverage. There is another reason where a double conversion design is advantageous, and that is in the area of gain distribution. One of the things I learned while working at Rockwell-Collins is never to have more than 80dB of gain at any one frequency; to distribute the gain at a couple of intermediate frequencies makes for a more stable receiver, as long as your circuit board layout provides for proper isotation between stages. I know that if a multiple conversion design is used, careful attention must be paid to selection of intermediate frequencies, in order to minimize the amount of in band spurs out of the mixers. What you said is on base, but I just wanted to add a couple of points.
As far as your comment on direct conversion "phasing receivers" this appears to be the way that modern receiver designs are going; the Collins 95S receiver is a direct conversion design that covers from 5KHz to 2GHz, with demodulation taken from the I and Q signals being handled by a DSP, as well as the IF bandwidths. I have heard this receiver while I was working at Rockwell-Collins, and I can attest to its performance.
Thanks for letting me throw my "two cents" worth in; it's good to see people looking at new frontiers!

You got a number of replies on this, all of which were good. I want to
add:

be sure you found out what caused the regulator to fail

This regulator supports current limiting, and even current foldback. In
a properly designed circuit, it should *not* have failed. I suspect you
may have a pass transistor which has also failed.

Anyway, just want to prevent you putting in a new IC and having it fail
right away.

Mike

Yep, that's the way I see it. I'd be really reluctant to try to put
something like that into production because the freq shift isn't very
well controlled, but for hobby/learning applications it's probably
fine. If you did it with, say, a 50MHz crystal, I'd expect it would
shift on the order of 1kHz or less. You can get a lot larger shift
using a varicap diode.

Cheers,
Tom

Reg,

The replacement for the MC1723CP should be the LM723 from
National. If you go to "http://www.digikey.com" and do
a search on "lm723" you can find them. I don't remember
what kind of package the MC1723CP was but it looks like
DigiKey has the 14-Dip, TO-99 and TO-100 versions.

However, be very careful about suspecting the "723". This
has always been a very reliable chip and seldom is the problem.
Usually the problem is in the feedback. But then, they only
cost $1 each so it may be just as easy to change it. The
spec sheet for the "723" is also available on the DigiKey site.

Is it a 14 pin DIL chip? It's probably the Motorola version
of the 723 regulator. The LM723 should be a suitable replacement.

About 40p from Grandata or about a quid from Viewcom.

3720. Re: Pls explain -- eliminating hum in speech amp?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-09 00:00:00 UTC
From: Bob <balbert@cnmnetwork.com>
Message-ID: <W46S4.69180$MB.1448995@news6.giganews.com>
Source record: 60755
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

The rationale for that hint is that some tubes have heater-to-cathode leakage that causes hum in the amplifier. Raising the heater potential reverse biases the parasitic diode that the heater and cathode create, and prevents current.

The whole thing is rather worthless actually. If you have hum from that cause, you need to replace the tubes with good ones that don't have heater-cathode leakage.

The amount of potential required is such that, even on the peaks of the heater supply, the diode never gets forward biased. So the value given applies to 6.3 Volt systems.

In general, if you have hum, the way to eliminate it is first to find the cause, then take measures to eliminate it. The scheme above only works if that's the source of the hum.

3721. Re: Build: Inductance Meter

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-09 00:00:00 UTC
From: Bob <balbert@cnmnetwork.com>
Message-ID: <Sf6S4.67882$VR.1355309@news5.giganews.com>
Source record: 60756

There are many ways to measure inductance. If you want to have a digital voltmeter indicate inductance directly, you need to supply a constant current to the unknown inductor, at a frequency where it has reasonable Q. The amount of current needs to be carefully calibrated so as to provide a voltage across the unknown that will correspond to the inductance directly. For instance, one millivolt per microhenry. You can make the calculation.

I wouldn't use a tuned circuit or a bridge, since the output from either will NOT be directly proportional to inductance, and therefore you won't be able to read inductance directly.

To avoid having to measure the high frequency with your voltmeter, you simply rectify it with a germanium diode and read it on a DC range. Due to the forward drop of the diode, you will have to have a fairly high current so that the meter will read several volts. Very xmall voltages across the coil will not give any output from the rectifier. You can, of course, add an amplifier and solve that one, but it will have to have a wide bandwidth, sufficient for any frequency you are likely to use.

Hi Leland,
The HO loop is actually close to a half wave in length. Resonance is restored by capacity coupling of the far ends. Pattern measurements (and modeling) show it to be eggshaped.

Hi, Joe.
You are applying a pulse each time you switch, correct? So, each relay can close a circuit when it is latched on, also correct? Why not make this the path to energize the next relay? That path will vanish once the relay switches and then the -next- relay will be the only one that can switch...

Cheers!

Anyone know why useable ferrite rods can't be homebrewed---anyone have experience making their own?

I'd like experiment with rods .75" in diameter and 12" long or longer for VLF/HF but I sure don't want to pay the big money asked for them---some rods go for $100! I've heard of lab bench work where ferrite powder is mixed with epoxy then poured into molds. Although I haven't priced powder I suspect it's a small percentage of cost in the finished component.

>radio to work on MARS frequencies.....thanks

I think I still have a copy of the manual for a Midland model #13-510, and,
if I remember correctly, it has a schematic in it. Drop me a note at wa4qal
at ix.netcom.com to give me your address and I'll see if I can get
it copied and mailed to you.

As for moving it over to the MARS frequencies, I think you're going to be
out of luck. I don't recall any jumpers or any other way to change the
synthesizer to enable it for out of band work. You might be able to rewire
the synthesizer, but finding information on the synthesizer chips might be a
bit hard to do; after all, the radio is about 25 years old now.

Brad OM,

I highly recommend you take a look at the "R2" DC phasing receiver, originally designed by Rick Campbell, Jan 93 QST. You can get the bare boards from Kanga. Hundreds of these receivers have been built. I am very pleased with mine. I am getting 50 dB of opposite sideband rejection with it, by hand-selecting the audio phase shift and diplexer parts. Single-signal reception does not mean you must use a much more complex superhet design! And, the beautiful sounding audio of DC receivers is a plus.
Also, save yourself from building and tweaking LC-tuned LO's. Build a simple AD9850-based DDS VFO, as described on the NJ QRP web page. It is Pruett's design from QEX article, as improved by AA0CD and others. Covers DC to 30+ MHz in 1 Hz steps, with LCD display (for those who feel they just have to have a "display" of something). The board for this VFO is also available from Bill Kelsey at Kanga, I think. Together, these two make a really nifty receiver for any band(s) of choice.
Also, providing for several bandwidths is much easier at audio (no crystal filters to build or buy), and with DSP back ends coming along, why fool with a superhet design any more?
73 and GL,

3732. QRP AMP 30 with a LARGE SWR

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-09 00:00:00 UTC
From: Curtis Scholl <cscholl@izzy.net>
Message-ID: <SjVR4.1018$R12.19697@news.itd.umich.edu>
Source record: 60824

Hello

I own a Ramsey QRP 30 CW transmitter. It can produce about 1 watt of power. I have it driving a Ramsey QRP AMP 30. This is tied into my MFJ Transmatch/SWR Bridge.

When I connect the Transmitter directly to the transmatch, I can adjust the minimal reflected power down.

When I connect the transmitter through the linear with the linear direct to the transmatch, I can not get the reflected power adjusted out. The SWR reads at 5:1. I can adjust out some but it is still at 3:1.

My antenna is a multiband dipole cut for 10.108, 14.060, 21.150 and 28.200. There is a balun at the apex of the inverted "V". The balun is rated for more power than my Heathkit can produce.

Why is it that the linear is affecting the reflected power so much?

I have a theory. The linear uses 2 FETs in a class C (? on type), one fet for the positive going pulse and one fet for the negative going pulse in a wideband transformer arrangement. If one of the FETs fails, could it cause a clipping of the signal at the neutral point thus producing peaks at 1/2 the fundamental and therefore causing a high SWR due to the lower frequency?

Has the Balun gone bad? I would hope not as the transmitter has no problem with high SWR.

I have gone over all the connections with a fine tooth and on the questionable ones I backed the solder up with a piece of copper wire to insure the trace conductivity.

Thanks in advance for your help.

You mean that Lilienfeld's transistors were unreliable and had very
low gain, usually betas less than one, and the FETs were poor also.
However, he clearly knew what he was doing; after all, he had at least
three patents in his favor, about 20 years before someone copied his
patent wording...

3735. New Resource For Investors

Newsgroup: rec.radio.amateur.homebrew

Hi,

I would like to introduce our new site and kindly request
that you add InvestMove.com <http://www.investmove.com>
to your Links/Resources page (or please forward this message
to the person who is responsible for maintaining your Web
site). This will provide your visitors with a very useful
and information packed resource. InvestMove.com allows
investors and analysts free access to vital stock market
information.

In recognition of its usefulness, InvestMove.com has been
awarded recently with the prestigious USA Today Hot Site award.

InvestMove.com features a unique tool that allows visitors to
enter a company symbol into a search form and obtain a customized
page covering more than 30 major information categories about
that specific company. The information includes: stock quotes,
stock performance, earnings estimates, stock valuation, company
performance, analyst opinions, broker reports, company profile,
and much much more.

Another feature of the site is an investor resources directory
that includes links to the best investment sites on the web.

Linking to InvestMove.com helps you to add value to your website
by presenting your visitors with a useful free investor resource.
Your visitors will find here all the tools and information needed
to make educated investment decisions, and it's all completely free.

In addition, links to relevant and popular sites are known to
increase a Web site's "popularity ranking" in some major search
engines. In other words, linking to http://www.investmove.com may
actually help increase your Web site's rank in certain search engines
that record this external link.

Thank you in advance

Meir Liraz,
InvestMove.Com

Some things to think about.
1) Many SWR bridges do not read accurately in the presence of high
RF. RF leaks into the circuitry and makes all meter readings high.
This is especially true if there is a lot of RF on the outside
of the coax or the antenna is near the shack.
2) Any signal from the amplifier that is not on the "transmit" frequency
will give a high reflected power. Non-linearities, harmonics, oscillations
due to poor neutralization, or arcing at a bad coax connection can do
this. A spectrum analyzer might be very helpful.

Dale, do you know anyone who uses the M-Squared 6m Ho-Loop for mobile work?
What I have for my apartment (homebrewed 1/2 wl loop) works OK, but will not
standup to a mobile application. I have been looking at mobile 6m antennas
for SSB use and the M-Squared design is one of them.

So what he's got here is a (fairly) standard crystal controlled oscilator that has its frequecy modulated by the incomeing code? I'm assuming that the code is binary and therefor this circuit would act much like an FSK transmitter. I think.

I don't have a direct answer, but how about stacking toroids or pot cores
to get the diameter and length you want? Maybe fill the hole in the toroids
with rods. Use ferrite glue to put them together.
I've been told that rods have an air gap from end to end, so why would
a gap in the middle make any difference? I don't know, what do you think?

Hello,
i would like to build a digital inductance meter, which could measure
with reasonable precision. The range would be 1nH to about 1mH and i was
thinking on a schematic like this

coil -> oscillator -> "frequency meter" , PIC -> 7seg Display

I saw a project similar to this one on Elektor Electronics but which uses
a PC to make the measure and display of values.
What do you think about this? And using a bridge to make the measure?
I don't have access to "those old QST numbers" :), so IDEAS instead of pointing
me to those are very welcome :)

Reg,

It's a very common voltage regulator. It's been around for a long long
time. Motorola part number given, but almost every analog company out there
made or makes a variant of it.

Reg,

Your "mystery part" is a common 723 voltage regulator IC.
Most any parts house (including Radio Shack) should have
one. MC1723CP is a Motorola number for the generic part.

Look for LM723, or even just 723, instead (or as well).

This is a very common voltage regulator made by many companies - and
each company sticks their own prefix and suffix on the base part
number.

A little more specifically, look for LM723 or other "723" voltage
regulators, preferably in the same package as what's in your PSU...but
if you can't get the same package, don't despair. If you get the pin
assignments for both package types, you should be able to match up the
pins properly and arrange some sort of mechanical kludge.

Cheers,
Tom

Get the hell out of radio groups you jerk spamer!

3754. Pls explain -- eliminating hum in speech amp?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-10 00:00:00 UTC
From: JGinNY <jwg6@cornell.edu>
Message-ID: <3918B94F.A9DE02AA@cornell.edu>
Source record: 60759
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

An old ARRL Hints & Kinks book includes a tip on getting rid of speech-amp hum.

Basically, it involves putting a 10 to 12 volt + bias on the filament circuit. The bias voltage is obtained by connecting 2 series resistors (as a voltage divider) between the plate supply and ground. This low + bias is tapped off the voltage divider at the juction of the 2 resistors, and then goes to the filament supply for the speech amp.

The article advises that this will do away with the hum, *but that the filament(s) must not be grounded on one side. (Neither should the center tap of the filament winding be grounded.)

Question is:
If this +10-12 volt bias is placed on the filament supply, how does that reduce or eliminate hum in a speech amp?
The wave shape of the AC component on the filament remains the same, does it not? It's just being bumped up by +10 volts throughout its cycle. How would that alone be effective in getting rid of hum?

And -- isn't one side of a rig's filament supply grounded, typically? How, then, could one successfully apply the aforementioned scheme?

Finally, one other point: The article recommends using a "filament bias" value of +10-12 volts, as mentioned above. However, it doesn't specify whether this is intended for 6.3 or 12 volt filaments. Would it matter? Would the same value of bias work for either?

many thanks,
N1AEP

Who says its a frequency shift keying circuit. A few millivolts
change in DC input will shift frequency but will also change
amplitude.

The circuit is much more likely to be an on-off, mark-space keyer
where a bit of chirp doesn't matter. The keying input signal could
then be several volts to turn the transistor fully on or fully off
with everything under well-defined control.

Curtis: I think you may be on the right track, but I suspect that the amp is generating some form of VHF parasitic signal. There is a very simple way to see if this is the problem: Get a purely resistive dummy load and check the SWR with this. If the amp is generating parasitics, you are getting a high SWR reading becasue the SWR is high at the parasitic frequencies. But with a purely resistive load, the SWR should be the same at all frequencies. If you get high SWR with the antenna and a low SWR with the resistive load, I think the parasitic diagnosis is strengthened. Good luck. Let us know what happens 73 Bill N2CQR

You probably need to take a look at the chip set manufacturers web sites. At this point the GPS receiver building process more or less consists of putting an RF chip together with an IF chip. A variety of people make some of each. Analog Devices, Sony, and Motorola all come to mind.

Hope this helps

I have been trying to get a friend to update my parts accumulated over
28 years for sale web site.

Here are two of the items I wanted to add:

6 - Ferrite Rods 0.4" dia. x 5.5" long Yellow code ferrite A2G ui=300,
for 0.4-2.0MHz use; tan~d/ui 150C; Ohm-cm = 1 x 10^7;
$2.50 U.S. funds each

6 - Ferrite Rods 0.4" dia. x 5.5" long Blue code ferrite A5N ui=100,
for 0.4-20.0MHz use; tan~d/ui 300C; Ohm-cm = 1 x 10^4;
$2.50 U.S. funds each

These are the longest ferrite rods I have that I am willing to part with.

Nothing special about a Nuvistor except its size. They are very tiny in an attempt to compete with transistors. RCA created the name, and at the same time, marketed their television receivers with the slogan New Vista.

They do require special sockets.

I've never seen a good history of the Nuvistor. But I'm not sure miniaturization was the primary focus. Remember, there were sub-miniature tubes available at the time the Nuvistors hit the market, and those sub-minis were used in plenty of portable equipment (such as hearing aids, portable radios, and those lunchbox style walkie talkies that Motorola once made) whereas I can't think of something a Nuvistor was used in to provide primarily miniaturization.

Nuvistors were introduced at a time when transistors were not all that great at RF, so I'm not sure the "compete with transistors" theory works.

Certainly in Ham circles, the Nuvistor was used because it had low noise figure, good for VHF reception. When they were introduced, the only thing better, paramps and tubes like the 416, were far more expensive and finicky to use. Nuvistors beat out any common tube used in VHF front ends at the time. And this held true until good transistors and FETs arrived on the scene.

And while I've never seen one, I understand that Nuvistors showed up in some TV front ends, again presumably for the low noise figure.

The miniaturization of the tube might have provided the Nuvistor with certain performance increases, but my RCA Receiving Tube Handbook barely mentions the Nuvistor.

>Do the Nuvistor tubes have special characteristics?

Yeah. They're small. This leads to a few useful features. First, you don't need as much heat to fling electrons off the anode. That means they'll have a lower noise figure than most larger tubes. Second, their small size can help by presenting less reactance (of both kinds). This made them easier to work with at VHF frequencies.

Yes, I have seen them. They were commonly found on the front end of early high end television and FM stereo tuners.

I found one in a TV tuner, which is fortunate because the Clegg Venus that
I bought at a swapmeet had some kinda FET stuck in the Nuvistor socket.
The Nuvistor is small for the obvious reason of reduced element geometry,
hence lower inter-electrode capacitances and such. Great for VHF and up.
VHF noise figure is below 3db, I think.
Too bad my TV-10D/U doesn't have a socket to test it with.
Look up 6CW4 for VHF and most common, 6DV4 for UHF.

Yep, I jumped to the conclusing that the PLL receiver was looking for FSK, without looking very closely: clearly when the input is at 0, the oscillator is off. If the input were between, say, 2V and 3V, the FSK would make sense, but unless we know otherwise, a 0-5V cmos input level would be a reasonable assumption, and that's clearly on-off keying.

Cheers,
Tom

Jorge,

Nuvistor is a small (1 cm diameter) triode vacuum tube from the 1960s. Used in many VHF amplifier circuits, 2-meter converters etc.

3772. Re: What is a Nuvistor

Message-ID: <8fc8vpjpn1@neptunium.btinternet.com>
Source record: 60777

I recollect miniature nuvistors had characteristics of mu, gm and Rp
similar to full size radio receiving tubes except that they were
capable of working with 12 or 13 volt DC plate supply voltages just
the same as the cathode heater supply volts.

Fine for 1950 car radios when germanium transistors were very poor
ampifiers at RF. The better RF efficiency of silicon junction
transistors very soon dominated the market. Nuvistors were very good
in their day, but their day was short. A sad story ?

Hello--
Look for a uA723 or an LM723, or check the EGC cross-reference guide.
This should be a common IC and possily available at Radio hack. The
prefix (MC, LM, uA) indicates the manufacturer and the CP suffix
probably
indicates that the version you have is a consumer-temperature-range (C)
plastic DIP (P) version. You can use a ceramic DIp in place of a plastic

if that's all that's available.

If you can't locate one locally, I can help via mail order.

Rather than make your own, rods can be glued end to end, and you could
stack several rods together to get something like an effective 0.75"
diameter.It should work just as well as a single large rod.

There may have been some that were designed for low plate voltage
but the most common one, the 6CW4, required a plate voltage of
140-150 Volts. I still have a 2-Meter Converter that uses 2 or
3 of them. The power supply for it provides 6 Volts for the
filaments and 140 Volts for the plate. Last I checked the converter
was still working fine.

3783. An Icom IC-706 Tune Trigger for as low as $1.19 (Some assembly required)

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-11 00:00:00 UTC
From: wa2ehz@my-deja.com
Message-ID: <8feifg$4uh$1@nnrp1.deja.com>
Source record: 60698

An Icom IC-706 Tune Trigger for as low as $1.19 (Some assembly
required)

The ICOM IC-706 has a nifty feature built in to help the operator tune
the HF antenna SWR. By pushing the TUNE button on the front panel, the
radio switches to CW mode and transmits a 10 Watt carrier. This state
last for approximately 10 seconds or the operator can terminate sooner
by pushing the button again. This was designed to work with the Icom
automatic antenna tuners.

There have been a few circuits developed to fool the 706 into thinking
there is a Icom tuner attached and produce the same tuning signal which
can be used with a manual antenna tuner or many automatic tuners. One
is available commercially for about $35 and a new circuit appeared on
the Internet recently for home-brew.

Well, being the cheap guy I am, and being one to tinker, I felt there
had to be a simple way to do this. I began reading the various postings
on the Internet. I went back to an e-mail exchange I had with Ed, W1AAZ
in early April 1999 on Vartel's ICOM 706 Discussion Group. Ed explained
the functions of the TKEY and TSTR pins on the "AH-3" connector on the
706.

==========
e-mails:

RIG: ICOM 706 MKII
From: Ed, W1AAZ
Date: 04 Apr 1999
Time: 20:20:35

Every thing you need is available at the AH-3 connector and a couple of
dollars from Radio Shack.

< 0 0 0 0] <---- connector TKEY TSTR 13.8V GND

TSTR must be brought high (tells the IC706 that an antenna tuner is
connected). Pushing the TUNE button then pulses TSTR low which can clock
a flip flop (configured to toggle)that drives the TKEY line low
(transmits a 10W carrier for 20 seconds or terminated sooner by second
push of the TUNE button). You need just a few more parts to provide the
correct clocking level(positive pulse) and to set the flip flop on power
up (so it always
comes on in the correct state).

RIG: Icom 706
From: Ed, W1AAZ

Date: 13 Apr 1999
Time: 08:39:27

Comments

>It sounds like setting the TKEY line low puts >the transmitter into this "tune mode".

No.....pulling TSTR high is what puts the IC706 into "tune mode". Thereafter, bringing TKEY low keys the IC706.

>If this is true, can TKEY be brought low by just >connecting to GND through a push button switch?

Yes...but see above.

>Would it have the same effect?

Yes.....in a limited way (manual tune via an external push button switch).

>If this were to work, can it connect straight to GND or should it have a resistor in series?

No resistor needed in TKEY line.

==========
I got an idea, went about experimenting and was pleasantly surprised. I played around for about 2 hours to find component values I wanted and trying to make the system not work. It worked fine. It was simple, too simple. I could not sleep that night. I was kicking myself for not trying this a year sooner, remembering all those times driving the RV switching to AM, reducing the power, keying the PTT, tuning the antenna tuner, then resetting it all for SSB and keeping between the lines at 55 MPH.

Then, the next "natural" thought came to mind: "SELL IT". "For $3.00 worth of parts, I could under sell the competition by $10.00 and still make $20.00 per piece for a half-hour's work. But this design was too simple, what if some one opens the case and looks inside, boy would they feel ripped-off." I finally had to wake the wife so she could share in my sleeplessness. I told her my idea. She asked about patens. Then I thought "What if this is what is in the commercial unit? I would be violating his paten if I sell it. What would it cost to research? What about product liability?" At that point I decided to drop the marketing plan, besides how many customers could there be? Do I want to spend my summer evenings building, packaging and shipping?

A half-hour later I decided to go downstairs for milk and cookies and turned on the TV. There, just when I turned the TV on, was a commercial seeking inventions. I had to chuckle, my mind was made up. I am not into ham radio to make money. What if all discoveries were released only for profit, where would the hobby be? The hobby is supposed to be to share knowledge for further advancement. No, this is not going to

change the hobby the way PSK-31 from a PC sound card will, but it's the principle. Yes, there are lots of people in the publications and on the Net selling their wares, and that's great. I even had just ordered an add-on card to allow repeater splits to be programmed in the 706 (something Icom forgot in the first model). But this thing is too simple.

In order to assure nobody else makes money off of this, I have decided to post my findings on all of the news groups I can think of and e-mail various publications for printing if they choose. Of course, I assume no responsibility for any damage or consequences and there is no warranty. If you think this is worth while, enjoy. If you find a problem with the design, let me know and I will distribute to the same list that message uses. If you disagree with my opinions, that's your right, but I will not debate.

Well that was the price you had to pay for my 2 hours of experimentation, I got to be on my soap box. Like I said, this is simple. You can buy the Molex connector at Radio Shack (#274-0224) and any "Real Ham" will have the rest of the parts lying around on the floor. Use proper construction techniques, assure you have no shorts. How you want to package it is up to you. Use the above diagram of the connector as a reference. Connect TKEY to TSTR. Connect the negative (-) side of an electrolytic capacitor C and one side of resistor R to this connection. The positive (+) of C and the other side of R circuit is connected to +13.8V. That's all there is, a simple RC circuit between the TSTR/TKEY junction ant +13.8V!

Turn off the 706 and plug in the unit. Make sure you have some sort of load on the HF antenna connector. Turn on the 706, the radio sees TSTR is high during boot up and thinks there is a tuner connected. Push the TUNE button. The TUNE light should flash counting the seconds. Yes, you may interrupt the cycle by pressing TUNE again.

What is R and C? Well the higher the values, the longer the 706 stays in TUNE mode. The highest the R value I was able to use and still have the 706 think there is a tuner was 3.3 M-Ohms. I use a 1000 uF 16WV to get about 20 seconds of TUNE time, 440uF gives about 10 seconds. The values are not critical, but there are limits, so feel free to play using parts you have.

Two problems I found which I don't feel are "biggies": 1) If the 706 is allowed to finish the cycle, the TUNE light stays on - sometimes. This can be turn off if you hit the TUNE button soon after it finishes. If you wait too long, it will start a new cycle. 2) If you terminate the cycle early, to start a new cycle, you need to wait until the capacitor discharges or you can turn off the 706 and back on to reset.

How does it work? It becomes very obvious by re-reading the e-mail exchange above. The capacitor C just holds TKEY low while C discharges through R. In fact, if so desired, one can drive TKEY low externally to hold the TUNE state. This opens all kinds of possibilities for

automatic tuners that can sense the SWR. Low is below 2V according to my meter. Watching an analog voltmeter is very educational in this type of project. This is where you learn that if the cycle is terminated early by pushing the TUNE button, you cannot start a new cycle until TKEY is above 2.5V.

Thanks to Ed, W1AAZ for the explanation of the connector
If you have any comments, I'd love to hear them. Enjoy!

>
Really, I suppose they lasted until high-frequency FETs became
available. Nuvistors were used in the input stages of 'scopes, for many
years after everything else (except for the CRT) was solid-state.
Some of those 'scopes are still running, but if/when the Nuvistors go,
that is the end... unless someone has a secret cache.

One problem with Nuvistors was their short lifetime at higher anode
voltages. The 6CW4s in my VHF converters (remember those?) used to last
about a year - and then died very suddenly. At the time, it wasn't
always possible to tell whether the front-end had died, or it was just a
normal evening on 2m or 4m AM...

Hi guys, my name is Rick.
I wonder if anyone of you could tell how some HF vertical antennas could work without radials system. As an old timer ham (23 years of ham operation), I also built a lot of antennas, including some classic monoband and multiband verticales, but always with a radials, which, I think are acting like some kind of artificial ground. Few years ago, some antennas builders started to offer some kind of antennas (like CUSHCRAFT for exemple..R5, R7...etc..), which doen't have radials. I wonder if they are working in half wave lenght type, or with some matching devices with bring the imperdance to the appropriate value..????????
Please, if you know something about that kind of verticale antennas (without radials), drop me an e-mail......would greatly appreciate it
Regards and 73's to all
Rick

3790. 50 ohm to 5k ohm audio transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-11 00:00:00 UTC
From: fretman_2@my-deja.com
Message-ID: <8ff7bdtuc1@nnrp1.deja.com>
Source record: 60705

I've build a diode ring double balance mixer...50 ohms at each port. I have a Radio Shack Pocket Amplifier that I'm using for audio amplification...5k ohms input. How can I build a xformer to transform the 50ohms to 5k ohms audio???

Thanks!

Rick:

Check out my site http://kd4pwb.homepage.com . I built an RF Sig Gen
and the link for the circuit is on my site. You might be able to mod
it to get you to 30Khz.

That's true, I can do that, but at $20 a pop for a rod it's easy for
costs to topple well past $100.

>slow.....)

All of the LM series, as well as the BC-221 series, of WW2 frequency meters have excellent capacitors with integral 100:1 gear drives in them. Fifty turns to cover the band or band segment you desire. They are very solid, glass or ceramic insulated, and no backlash. Don't yank plates out - just put a ggod quality fixed capacitor in series and/or tap down on the coil.

I have built two receivers using these caps, and they are simply the sweetest dial going. You need a shaft extension and a nice BIG knob, as well as some sort of dial drum, but that's a piece of cake, really. My current rx has the VFO in a box made of 3/16" aluminum plates, and a dial drum made out of a piece of Plexigals tubing six inches in diameter. Plot lights inside the drum give a nice illuminated dial. The tuning scale is drawn on a piece of mylar sheet that is on the outer side of the dial drum.

Tuning rate is 5 to 6 kHz per knob turn (and the knob is a big solid Bakelite three inch skirted job.)

Also useful are the tuning capacitors in the ARC-5 transmitters. Almost as good as the LM/BC-221 jobs, plus a nice dial.

DON'T tear apart a good freqmeter or ARC-5!!! There are lots of junkers and parts to be had without doing that! Fair Radio had them last time I looked. Ask around!

Warning! If done right, these units will spoil you rotten. You will not be satisfied with the usual dials ever again.

Not really, Reg. You're confusing the special tubes made for that service in
the '50s with the tiny Nuvistors of the 1960s.

>Fine for 1950 car radios when germanium transistors were very poor
>ampifiers at RF. The better RF efficiency of silicon junction
>transistors very soon dominated the market.

True - but Nuvistors appeared after that was all settled. They lasted into the
late 1960s - early 1970s. They are much smaller than miniatures.

Although most were triodes, a few types were pentodes. There were 2, 6 and 13
volt heater versions of them.

They were the first and probably only tubes to be manufactured using a high
level of automation. They also used no glass - all ceramic-metal.

Thanks for the corrections Jim. After 50 years the memory plays
little tricks. But was I correct about the low plate voltages used by
nuvistors ?

I assume they didn't arrive on the scene until automated
precision-dimensions manufacuring methods had been developed for use
in other fields.

=========
Cathode current is the sum of plate current, screen grid current, and
control grid current (if any). The screen and grid current values are
fairly low -- check a tube manual for typical values. So cathode current is
essentually plate current. Perhaps Swan decided to get the meter away from
the high plate voltage and get it in a low voltage circuit -- just a guess.

The cathode meter measures total tube current, plate, screen and control
grid if the control grid is positive and draws current.

Quantity 50, of the (size) 82- ferrite toroids would cost about $60.00 *
with shipping.
Stacked this would be about 12" long.
Anyone have opinions on how 50 toroids stacked would compare to a
3/4"x12" rod?

* see http://bytemark.com/amidon/prfcore.html

3813. Re: Can You ID this tube?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-12 00:00:00 UTC
From: Bob Weiss <bweiss@carroll.com>
Message-ID: <391C9C2C.3FF64770@carroll.com>
Source record: 60652

The type number of this tube is simply 15E. The rest of the designation on the box indicates joint Army-Navy (JAN) specification, and manufacture by Eimac (CIM). The tube is also designated as types 4C30, 8023, or 3-15A3.

It is an internal anode UHF transmitting triode, originally designed for use in WW2 vintage radar equipment.Filament ratings are 5V@4A, maximum plate dissipation 15W. The 2 pins at the bottom are filament connections, the top pin is the grid, and the side pin is the plate.

There are the tradeoffs. Higher If and image rejection. How about
going to 10.7 mhz with a ceramic filter for image rejection and then
down to 455 for the final sideband filtering?

I can't speak for the 570 but I do have a 706mkIIG and unless you are
interested in its capabiliites in going mobile and working vhf and uhf you
would be better served going for a larger hf only rig. I considered the fact
that I was getting a 6m, 2m and 70cm all mode just as important as getting
another hf radio. Even with the front panel light turned off, mine runs warm
to the touch, even when just sitting there on receive. The button interface
requires either short or long presses on the buttons, so I wouldn't
recommend it to anyone with any kind of shaky hand. It also took a little
getting used to cycling around the menus and I wouldn't even try to do that
mobile.
I have mine feeding a tuner so I don't know how well it handles high swr.
thanks, John.

3820. make money

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-12 00:00:00 UTC
From: 4Roses@Access1.NET
Message-ID: <391B4C41.41C66814@Access1.Net>
Source record: 60711

Make $1000 of an initial $6 investment very easy, not a scam, really works!

Make Money Now! It doesn't get any easier than this. Just follow this awesome money making program, and you'll be collecting a nice supplemental income in no time. You don't have to buy anything! You don't have to sell anything! This is not a Paid To Surf Program or a Paid to Click Program. You don't have to surf the Internet for a ton of hours or click on little banners a million times. This program is fast, simple, easy, and most importantly....IT WORKS!

Mission: To make a one time investment of $6.00 and have it return to you over $6,000.00

The program really works! Read this testimonial first!
A little while back, I was browsing through newsgroups and websites, just like you are now, and came across an article similar to this. It said that you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, "Yeah right, this must be a total scam." But like you and me, i was curious, so i kept reading. Anyways it said that you send $1.00 to each of the 6 names and addresses stated in the article. After you send the mail, you then place your own name and address in the the bottom of the mailing list and post the article in at least 200 newsgroups. No catch, that was it. So after thinking it over and talking to a few people about it, I figured, "what have I got to lose other than $6.00 and a few stamps?" So I decided to try it and I mailed out my measly 6 bucks. Well Guess What?! Within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. Mail after mail with a 1 dollar bill inside. In the first week, I made $25.00 - Wow, I already made back my initial investment with some extra lunch money. But next week came more mail. By the end of the second week, I had made over $100! In the third week, I had over $1200.00 and it was still growing. By the end of the 4th week, I had well over $6,000.00! I couldn't believe it. It was certainly worth $6.00 and 6 stamps. And the best thing - it's perfectly legal! Thanks a bunch to everyone involved!

Important: This is not a rip-off; it is not indecent; it is not illegal; and it is 99% no risk - it really works!
Please note: Please follow the directions EXACTLY, and $6,000.00 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions.
You will now become part of the Mail Order business. In this business

your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you asking to be included in that list.
4 Basic Steps to Success
STEP 1 : Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Write on each piece of paper your mailing address and your email address. Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase with
your house and email address. What you are doing is creating a service. THIS IS ABSOLUTELY
LEGAL! You are requesting a legitimate service and you are paying for it! Any doubts? Please refer
to Title 18 Section 1302 & 1341 of the Postal lottery laws or call the US Postal office at 1-8000-725-2161.
STEP 2 : Mail the 6 envelopes to the following addresses:

1) Christopher L. Sloan
2200 Hickory St.
H.S.U. Box #14579
Abilene, TX 79698

2) Karen Lohning
155 Blue Spruce Ct.
Delaware, Ohio 43015

3) B. Stoltenberg
7149 Wynter Way
Indianapolis, IN 46250

4)J. Hanan
10871 Poyntell Cir.
San Diego, CA, 92131

5)Rob Barnes
14575 Spingvale st.
Poway, CA, 9206465t

6)Eric Larose
17757 Corazon Pl.
San Diego, CA, 92127

STEP 3 : Now copy this list and take the #1 name off the list that you see above and move the other names
up (6 becomes 5, 5 becomes 4, etc...) and add YOUR name as #6 on the list.
STEP 4 : Change anything you need to, but try to keep this article as

close to the original as possible. Now try to post your amended article to at least 200 newsgroups (chat rooms, message boards, guest books, bulletin boards...u know). You don't have to post 200, you can do more or less, but remember, THE MORE YOU POST, THE MORE CASH YOU MAKE! Keep a copy of these steps for yourself, and whenever you need cash, you can use it again, and again.
PLEASE REMEMBER : This program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Loook at it this way. If you are a person of integrity, the program will continue and the CASH that so many others have received will come your way.
NOTE : You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes peple send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft. So, as each post is downloaded or read, and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousand of dollars!! What an opportunity for only a one time investment of of $6.00 and six stamps. Send it now, add your own name to the list, post it, and you're in business!
To make sure you don't get into trouble with Uncle Sam, make sure you declare your extra income. Remember, this is LEGAL> You are using the Internet to advertise your business. What is that business? You are creating a mailing list of people who are interested in home based computer and online business and methods of generating income at home. Remember, people send you a small fee to be addesd to your mailing list. It is legal. What you do with your list of names is up to you. so build your mailing list, keep good accounts, declare your income and pay your taxes. By doing this you prove your business intentions.
How Much Can I Really Make?
Out of 200 postings (which should take no more than 1 hour) you receive only 7 replies (a very low percentage). So then you just made $7.00 with your name at #6 on the letter. Now each of the 7 people make around 200 postings with your name at #5 and 7 more people respond, you just made $49.00. Now those 49 people put up another 200 posts each, and still only 7 more reply from each person, you just made $343.00 with your name at #4. Following the same pattern, you would make $2401.00 with your name at #3, $16,807.00 at #2, and $117,649.00 at #1. And remember, that's only if 7 people reply each time!
Additional NOTES :
1) In some countries, the export of the country's exchange is illegal. But you can get the license to do this from the post office, explaining the above statements (that you have an online busines, etc.). You may have to pay an extra tax, but that's OK, the amount of the incoming CASH is HUGE!!
2) You may want to buy mailing and email lists for future CASH, or

database of spreadsheet software.
3) You may eventually want to rent a P.O. Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it. Just make sure all the addresses are correct.
4) If you're really not sure or still think this can't be for real, please print a copy of this article and give it to someone who really needs the CASH, and see what happens.
5) For a business to be successful, be honest and fair.

Source record: 60714

You don't need a transformer. If the diode ring needs to be
terminated with 50 ohms for correct operation then just connect a 47
or 56 ohm resistor across it. But very likely there's no need.

The amplifier could not care less what impedance is driving it. Don't
listen to scary old wives' tales about impedance matching at such
points in the circuit.

Message-ID: <391BFD68.9559F799@lafn.org>
Source record: 60717

Great news,

My friend Hugh, W6WTU has solved his "RF Sponge-QTH problem and
wishes to thank everyone who made suggestions.
The following message is from W6WTU, Hugh Wells.
Thank you EVERYONE for your help.
73, W6MIK
--
David Shalita (Dave)
af389@lafn.org
Van Nuys, CA

================
Please forward this note to Hal and EVERYONE on Digests
as they perhaps will be interested in what has been done to find
and resolve the RF Sponge situation at my house.

Hal was absolutely correct about my "house" location NOT being an RF
Sponge. I appreciate his effort and attention to my problem.

As a quick history summary, we've been chasing the RF Sponge situation
for a little over two years and have now resolved the problem with the
repair of the 12db Comet antenna. A solder joint had come apart in the
upper 12-foot section and even with the internal components laying out
on the ground, the problem wasn't evident.

While measuring the values of the internal disc capacitors I discovered
the bad joint and sweat it together with solder. The antenna now
exhibits the 12db design gain as it should.

To actually pin point the antenna as a problem required some lengthy
antenna range monitoring and comparison with known antennas along with
another repeater site located two miles north.

For antenna gain comparison tests, I built up a folded dipole which
exhibited a 3db cardioid pattern, and a 5-element Yagi with a design
gain
of 9db. The 12db Comet compared equally with the 3db folded dipole and
failed against the Yagi. BTW: VSWR never appeared to be an issue and
was below 1.8:1 on all antennas - even the bad Comet.

The test method used was to operate the respective antennas in a
receiving mode while keying up three remote repeaters individually
located beyond 25 miles and spread equally across a 170 degree
horizontal
plane. Signal strength and noise was compared between each of the three
sites as well as to how each antenna performed relative to each site.

The repeater located 2-miles north was the one operating as desired and the plan was to achieve the same receiving results from the "house" location since the two locations are of comparable height and view of the terrain. That has now been achieved.

While monitoring mobile stations some 30 miles away through the repeater and simultaneously through the "house" receiver, the signal level and popcorn noise are nearly identical for all of the mobiles.

Therefore, it appears that the RF Sponge issue has now been resolved with the repair of the 12db Comet antenna.

Thanks and 73
Hugh, W6WTU

If you're a Hamvention vendor who plans on selling QRP equipment please
contact me at KI8IK@arrl.net. I'm compiling a list of QRP vendors for
subscribers of the QRP-L reflector. This will help them easily locate
you among the thousands of sellers in attendance.

Items of interest include:

Used QRP gear.
CW keys and keyers.
Portable HF antennas.
QRP books.
Gell cells/chargers/solar cells.
Workbench supplies/soldering stations.
Parts for homebrew (transistors, var caps, PCB stock)
Crystals near QRP frequencies.

3833. Re: 50 ohm to 5k ohm audio transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-12 00:00:00 UTC
From: fretman_2@my-deja.com
Message-ID: <8fhiemfun1@nnrp1.deja.com>
Source record: 60724

I'll give the 50ohm resistor a try.

It's not especially that I'm concerned about the DBDRM (double balance diode ring mixer) seeing 50 ohms...I'm more concerned about the level of the signals coming out of it. The CW signals that I'm after are very faint.

Here's the setup....rf pre-amp & homebrew vfo into homebrew DBDRM with audio into Radio Shack pocket amp...a direct conversion receiver I guess.

Here's what I'm doing. Say I hear CW on 7.110 on my SW receiver. I tune my homebrew VFO to 7.100Mhz which is inturn injected into the DBDRM. The antenna jack of the DBDRM is connected to an RF preamp. The audio at the other end is heavily loaded with broadcast band stations and very little CW (I can copy the CW but the audio faint). Big SW stations boom when I tune across them and I have to cut back on the drive of the VFO to stop the howl. I'm thinking the faint CW audio may be the impedance mismatch but it may be another problem.

If I terminate the 50ohm port on the DBDRM I'm still faced with transforming 50ohms to 5kohms.

I'd like to get rid of the BCI but that's down on my list for right now. I'd like to get a better copy on the CW signals first.

Thanks!

Bill

3834. Question: Innovation in Amateur Radio

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-12 00:00:00 UTC
From: Kevin McQuiggin <mcquiggi@sfu.ca>
Message-ID: <391C479A.ED335B9A@sfu.ca>
Source record: 60725
Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.misc,rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew,rec.radio.amateur.space,rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.dx,rec.radio.amateur.antenna

Hi Folks:

I've been licenced for 23 years, currently VE7ZD, and am in graduate school up here near Vancouver, BC.

I'm researching amateur radio and its history. I'm specifically interested in inventions, discoveries, or techniques that were developed within amateur radio and later spread to the electronics industry. Similarly, some of our operating techniques and procedures were later widely adopted by other services.

Hams operate outside of the structured environments within industry, and I think that this freedom has permitted us to invent and discover without being shackled by any policy issues, or possible stigmatism from investigating things that would be considered "too far out in left field" by management and non-ham co-workers.

Examples would be the investigation of wavelengths below 200 meters, with the discovery by hams that such wavelengths were better for propagation than longer waves; packet radio; APRS; propagation studies that were undertaken in the 20s and 30s; facsimile; SSTV; and network operating techniques.

Some of this stuff was regulated, such as the banishment of amateur radio to the "useless" wavelengths < 200 M, but this sort of proves my point. There's been lots of innovation within the hobby, and the general public now benefits from it.

If anyone could provide me with more examples, or good books or articles on this topic, then that'd be great. Of course I'll give appropriate credit to those who assist!

If you could email me as well as posting your reply, thanks. There's lots of traffic in these groups and I don't want to miss any replies.

73,

Kevin VE7ZD

How about if I start you off with a pointer to a piece by the guy who invented SSTV, Copthorne Macdonald, VY2CM, in his own words. SSTV was invented at the University of Kentucky, in Lexington, Kentucky.

Dave

P.S. Standard Disclaimer: I work for them, but I don't speak for them.

3838. Re: 50 ohm to 5k ohm audio transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-12 00:00:00 UTC
From: Tom Bruhns <tom_bruhns@agilent.com>
Message-ID: <391C53CB.EE529DCF@agilent.com>
Source record: 60729

It's good to terminate the diode mixer with 50 ohms to keep spurious responses down. You can do that with just a resistor. In fact, it's best to terminate it at all frequencies into 50 ohms, assuming it's designed for that, and the resistor will do a good job of that.

As for amplifiers, once you've terminated the mixer properly, you can use about any amplifier. The amplifier "doesn't care" what the source impedance is, especially if it's lower than the rated input impedance. Your source impedance will be the mixer load resistor in parallel with the diode mixer output (source) impedance, likely about 60 ohms or so if you drive the RF port from a 50 ohm source.

Now where that all DOES become important is from considerations of noise. Maybe you'll want to try to improve things in this area once you get it basically working. If you're trying for the best possible sensitivity, you'd want to pay close attention to the input voltage noise of the following audio amplifier: the lower the better. If you look up info on what the stereophiles do for "moving coil cartridge" pre-preamplifiers, you'll be on the right track (if you avoid the hype...a bit difficult to do!). Some of them use transformers to step the source impedance up a bit, and some just use amplifiers designed for lowest possible voltage noise: you can get down to perhaps 0.5 nanovolts/rtHz, but I can about guarantee your Radio Shack amp will be up above 10nV/rtHz. If you want to get into a more optimum amplifier for that sort of work, a good place to start might be an Analog Devices AD797 op amp, which gets to about 0.9nV/rtHz audio-range noise and is extremely low distortion to boot. I believe the data sheet, available on AD's web site, will have plenty of applications circuits. There are some other audio op amps that have pretty low voltage noise and are cheaper and maybe a bit easier to get. Even the venerable NE5534 is pretty good. You can build a "preamp" stage to add in between your mixer output and the Radio Shack amp...just a non-inverting op amp configuration with a gain of 10 or 20. -- It's also good to have a simple low-pass filter between the mixer output and the audio amplifier input, in case there are any fairly large RF-range outputs from the mixer which can get rectified in audio amp input stages and cause troubles.

Cheers,
Tom

3839. Can You ID this tube?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-12 00:00:00 UTC
From: "Mr. Wires" <NOSPAMwires@bigfoot.com>
Message-ID: <391C575A.4AC452B2@bigfoot.com>
Source record: 60730

Can anyone identify what kind of tube this is & what it was used for?

It's marked "JAN-CIM-15E", & carries the "Eimac" brand. Markings
(ratings?) stamped on one side of the box read:

Ep = 1000 v

Ip = 0.5 ma

Eg = "46" is written in pencil here

"Peak a - 46" is also written in pencil at the top of all these
markings.

I have posted pictures of the tube & box at:

http://members.xoom.com/_XMCM/studio_tech/tube.html

I am guessing that this is some kind of transmitter tube.
I have a number of these NIB. Are these only good for
target practice?! (I found them at a garage sale).

Thanks,

Mr. Wires (post here or delete "NOSPAM" to e-mail)

Tom:

Thanks for the help!!

This project is the fartherest I've ever gone with building my own homebrew receiver. I have in mind, once the rcvr is working properly building a keyable rf amp for the transmitter portion....making an xcvr.

I definetely will put a 50 ohm resistor from the audio output to ground.

BTW...what is spurious responses???

Thanks!

Bill

>[stuff deleted]

Packet radio already existed. Somebody (I can't remember his position
or whether he was a ham) in what was then the Department
of Communications here in Canada, with a name like deMercado, had had
some experience with Aloha Net in Hawaii. He decided it was time
for hams to move forward, and so he changed the rules in Canada to
allow packet radio, and introduced the Digital License. That license
carried no code test, but what was said to be a more complicated
theory test, and was VHF only, maybe restricted to certain bands. I
thought there was also a segement or two set aside for packet that
only Digital License holders could use. I remember he came and talked
to one of the local clubs in 1977 or 78, so long ago that the details
are vague.

So it's debatable how much ham radio influenced packet radio. On
the other hand, I don't dismiss the value to some individuals, who
got it going in ham radio and played with it, and used that
experience in the commericial area.

I think the influence of ham radio on technology in recent years has diminished. That's less important than whether it is still affecting the young, getting them interested in electronics and radio at a young age and providing them with a place to play with these things.

But up till a certain point, ham radio was basically synonomous with electronics and or radio. You don't have to go any further than Howard Armstrong, who was a ham first and it could be said his work was nothing more than an extension of ham radio, even if it influenced radio tremendously; regeneration (and regenerative receivers) the superheterodyne receiver, the superregenerative receiver and practical FM. You can't do anything in radio without one or more of those things.

A lot of the oscillator circuits are named after people who happened to be hams.

I thought practical narrow band FM for two way communication came from a ham, something like the guy who started Sonar, but that is based on some remembrance.

Amateur satellites certainly must have helped the field. The first OSCAR went up only a few years after Sputnik and must have cost significantly less. The concept of a piggyback launch came from OSCAR, and certainly others have taken advantage of that. There have in recent years been "OSCAR-type" satellites, ie relativley simple and inexpensive, which have probably been mainly experimental but have either helped provide a training ground for satellite work or helped "third world countries" in some way.

And you can find examples of hams supplying practical experience (gained from the hobby) in some of the important projects of the last century. I can't get to it easily, but I read a book about Benchley Park during World War II where they worked on what the other side was doing, and the author mentions right at the end the importance of hams in the practical experience they brought to the process. I think there was a similar mention in a book about radar development during WWII. People would come out of the universites, and know all the theory, but be lost when it came to practical work, but hams had that down because of building their own equipment. And of course when WWII started up, hams ended up filling various technical roles in the armed services.

I thought the first person to play with radio astronomy was a ham. If it was't someone who followed up was.

The US Army tried moonbounce in the forties or fifties, but they needed big arrays and lots of power. Hams followed, using much simpler equipment. I'm not so certain moonbounce has much practical use for society other than hams, since others can put up satellites while hams are somewhat limited, but the process of advancing the art may be as important as whether the technology actually migrates elsewhere.

A lot of the history has been written. The ARRL had or has some books on the history, including that one about "200 meters and down...". "Empire of the Air" by Tom Lewis (and it was a Ken Burns PBS show some years back) dealt with Armstrong, Sarnoff and DeForest and probably is fairly available. There was a book about Armstrong, I can't find my copy right now, first published in the fifties and then in the sixties by Bantam Paperback, that I've found in used book stores that provides good, though not too technical, coverage of his life.

Since you can now get QST easily on CDROM, it would be worth getting the early years, actually get the whole set if you've got the money, and then you can see the history unfolding as it happened. The other ham magazines may not be as useful, since they came later, and more important they aren't as available so cheaply or conveniently.

Once you have the ham history, then you can start exploring where it fits into the rest of electronic/radio history. Whether it was simply implementing something discovered elsewhere, or had impact on society beyond ham radio.

And you might want to dig up an article by John W. Campbell (yes the legendary editor of Astounding/Analog SF magazine) who was a ham and once upon a time wrote some technical articles for CQ. He once wrote an article about "How to be an Amateur" pointing out some of the benefits hams have to innovate for the simple reason that they aren't bound by corporations. I think it was published in an early issue of 73, and then reprinted once or twice. 1971 comes to mind.

That has certainly not been my experience with Amidon. Over the years I have spent at least $1000 dollars with them, including more than $100 in the past two weeks, and have had no trouble at all.

None.

Zero.

Zilch.

What's the difference between cathode and plate current values? Which is more useful in properly loading-up an RF tube amp?

Reason for this question is that I have an old Swan tcvr, and the meter reads cathode current, not plate current like I have seen on a lot of other rigs.

Would that cathode milliammeter be reading the current returning to the cathode (or B+ supply?) from the plate (across the load)? Or, would read the current _leaving_ the cathode through the tube, towards the positive plate?

The older radio handbooks I have don't mention "cathode current," per se; only plate current. What's the scoop?

mni tks!

Cathode current is a good way to measure because you can deal with much lower voltage with reference to ground. But be remember, when you measure cathode current you are measuring the total of the plate and grid(s) that make up the tube. The current flow is from negative to positive I.E. cathode to plate and cathode to grid(s). Hope this is of some help

Well... I have place many orders years ago with Amidon and I never had
any problems either. I often read reports like mine never thinking I
would resort to posting one---but take heed---there is a justifiable
cause.

Well... I made three more telephone calls today and I finally learned
that my order was shipped and presumed lost in the mail. I was told a
replacement order will be shipped Monday.

As best as I can determine Amidon has divided their operation into two parts serving business orders and personal or amateur orders. Why this is so is confusing---I was told at Amidon there was no difference in the orders that are placed.

Apparently, every time I called 714-850-4660 and inquired about a PERSONAL ORDER I was shuffled off to personal/amateur ordering---even though I asked for the individual who could help me with my order they could not transfer me to her because they are a separate operation NEXT DOOR (as I learned later)! Instead, I was hoplessly being transferred to other individuals with no capacity to help. It was my good fortune that I talked with a fellow in the WAREHOUSE who told me to call 714-850-7320. I did and I got another receptionist whereupon I was immediately transfered to the party I should have been talking to at the beginning of this week---twenty or so telephone calls ago---who resolved my problem in a matter of minutes.

I think the major factor in the problem I experienced is the NITWIT receptionist at 714-850-4660 who should have shown enough interest to direct me to their operation next door if I couldn't be transferred to the individual I needed to speak with. Oddly, my continued requests to speak with the one person who could help went ignored by her.

I think the operating structure of Amidon is seriously flawed---based upon my experience it is the epitome of poor business management. Unless they change their practices I will never, never, never place another order directly with Amidon but rather deal with their distributors instead.

I can't imagine that it would make a lot of difference. The control grid
and the screen grid will account for a certain amount of current, but
you're looking for a minimum reading when you tune the tank circuit.
All of the grid currents come from the cathode, but I think they're far
less than the plate current.

>Would that cathode milliammeter be reading the current returning to the

>read the current _leaving_ the cathode through the tube, towards the
>positive plate?

Assuming a grounded cathode, it would be placed between the ground and the
cathode. It's a reasonable arrangement because the meter doesn't have to
operate at the high plate voltage and thus doesn't need to be heavily
insulated.

An audio matching transformer from 50 to 5000 ohms will step up the
voltage by only 10 times.

In this day and age don't even think about winding 1000's of turns of
almost invisible wire on tiny mu-metal laminations. Just put an extra
transistor or 741 op-amp before or after the audio amplifier.

Yours Reg, G4FGQ

have lots of circuits, but isn't it much easier to convert a 2m PMR rig, they are available in large quantities here, and nobody want them

I've built several exciters, but later converted over a douzen 2m and 70cm FM PMR rigs to packet radio and 2m, 70cm and 23cm CW beacons

The problem with 'circuits' are that you also need a pcb, and constructional details, usually several pages of text with instructions. And every design need some special components, usually you won't be able to locate the coil formers required.

Converting xtal controlled PMR's you just remove all modulation stages, put some extra electrolytics on Vcc+ line to various power amplifier stages to avoid spurious emissions, and it is often experienced that the xtal oscillator is too noisy so at better approach might be needed

The PMR usually have some better selectivity against unwanted radiation of subharmonics from oscillator, amateurs very often don't seem to care, but you soon have a problem when Radio inspection has visited you after a TVI complaint at your neighbours. They've been here several times, although I only have 200W CW into a 17 el Tonna yagi.

I made a special modulator for keying some very high speed beacons with low key-clicks, it consists of two transistors, looks like amplitude modulator

3862. A way to make the Yaesu FT50 a repeater ?(simplex/parrot)

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-13 00:00:00 UTC
From: yo2llq <doiNOdoSPAM@internetcafe.ro.invalid>
Message-ID: <0704bbe1.7daa5ac0@usw-ex0109-068.remarq.com>
Source record: 60667

Hi there

Since the FT50 can't do crossband repeat(for design reasons
it just can't), there could be something to compensate
this... Like you could turn it into a simplex repeater(with
the aid of the FTT-12 keypad).
If you know a mod or something to turn the FT50 into a
parrot pse let me also know this.

Thanks Reg... OK on E & I cores... What I want to know is homebrewing ferrite rods of large diameter and length using epoxy and bulk powder. I was told of short lab trials doing it for evaluation purposes but I don't know what the tradeoff's are nor the results compared to rods manufactured utilizing conventional techniques---I suspect decreases in permeability. My references don't contain any manufacturing information.

3865. Help with MFJ-1278 and Kenwood TMV7

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-13 00:00:00 UTC
From: Pedro Braz <pqp@netcabo.pt>
Message-ID: <8fjfpsjfu7@duke.telepac.pt>
Source record: 60670

Hello,

I have a MFJ-1278 and a Kenwood TM-V7 and need to connect them both.

The MFJ 1278 Pin out is as follows:

PIN 1 - MIC. AUDIO
PIN 2 - GND
PIN 3 - PTT
PIN 4 - REC. AUDIO
PIN 5 - SQUELCH INPUT

The TMV7 Pin out is as follows:

PIN 1 - Packet data input(PKD) (TX data from TNC to transceiver)
PIN 2 - GND for PKD
PIN 3 - Packet Standy - TNC can use this pin to inhibt the transceiver microphone input while txing packet signals
PIN 4 - OUput of detected 9600 bps date 500mVp-p 10Kohm
PIN 5 - Same but for 1200bps (500mVp-p 10Kohm)
PIN 6 - Squelch Control output (Inhibts TNC data txing while transceiver squelch is open, Prevents interference to voice comms over the same freq. Output leve: Open Squelch +5 V high Close Squelch 0V Low.

They say the 9600 pin should be used when there is only one PIN coming out of the TNC for the data.

The idea I have of connecting them is:

MFJ TMV7
PIN 1 ---- PIN 1
PIN 2 ---- PIN 2
PIN 3 ---- PIN 3
PIN 4 ---- PIN 4
PIN 5 ---- PIN 6

IS ot ok? Should I do it another way???

I really need help.

73's and thx all

3866. Re: 50 ohm to 5k ohm audio transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-13 00:00:00 UTC
From: fretman_2@my-deja.com
Message-ID: <8fjj7o$k5r$1@nnrp1.deja.com>
Source record: 60671

I'll give the 741 op amp a try. I've got several 741's in my junk box
and I can put together an amp pretty quick.

I did put the 50 ohm resistor across the terminals and that did help.
I noticed too that when everything runs off of battery that I get much
less noise. I was able to copy CW at 7.040Mhz very plainly. The BCI
went down too on 40m but seemed worse at 10.106Mhz.

Thanks for the reply Reg!!

I have not been involved with anybody manufacturing ferrite products for a while so this may be out of date. Bulk powers are mixed in various ratios with binder matterial and then pressed into shape with a fairly large press. The result is cooked (fired) to turn it into a solid.

The key is that what you buy as a core is powder plus binder. To get the raw powder I would guess you have to order a couple hundred pounds of the stuff ... not cheap at all. If you just grind up a core you have powder plus binder. If you add epoxy to the binder then you get less net power per unit volume. Permiability would go down and may go down a lot. About the only way to find out is to grind up some cores and see what happens.

If I was going to do it I'd buy the biggest RFI cores Digikey sells, glue them together to get a 12 inch length and then put the epoxy plus ground cores down the middle of the assembly. That way most of the cross section is the real thing and only the center is homebrew.

Enjoy

Bob

A 10 times voltage step up is 20 dB and this case the performance of
the receiver is more or less dictated by the internal noise of the
audio amplifier, thus, not using the transformer will degrade the
signal to noise ratio by nearly 20 dB, not an insignificant number
even at lower HF, even though the background noise is still pretty
high.

>In this day and age don't even think about winding 1000's of turns of
>almost invisible wire on tiny mu-metal laminations. Just put an extra

Sure you can connect two 741's in series, each with a voltage gain of
100, but the output will be saturated with the noise from the first
amplifier, even without anything connected to the input.

The point is that you should use as much of the available signal power
as possible, thus, the amplification in the audio amplifier can be
reduced, reducing the internally generated noise contribution to the
output signal.

>

My concern is that the permeability with the epoxy may drop from 5,000 to about 50 or so.

Rod antennas are weird. The permeability of the core does make a difference up to a point. The only reference I have quickly at hand is the ARRL Antenna 18th edition. Page 5-7 shows a figure 12 that describes the relationship between rod permeability and core permeability. For a 10:1 length to diameter ratio you get very little benefit going from a core 1000 to a core 10,000 material. At the same length to diameter ratio the change from 100 to 1000 still gives some improvement in the inductor. If you go to a 100:1 length to diameter ratio then materials with permeability of 10,000 or so still give you some benefit.

The references they cite in the bibliography are by Polydorff and Snelling. I don't know if their stuff is any easier to find than an ARRL publication.

Time to do an experiment and see what happens ....

Enjoy!

Bob

Right you are Paul. The 741 will contribute about 5 millivolts of noise which will be amplified by the next stage. The poster had the right idea to start with. Instead of looking for a 50 to 5k transformer he should be looking for about anything with this ratio. Even a mic 10k to 600 ohm transformer would help a lot. If amplify he must I would go with a single FET per stage instaed of the op amp. They are a lot less noisy. Of course there are less noisy opamps than the 741.

For tetrodes and pentodes, the cathode current is greater than the plate current because of the screen current being added in. The control grid current is a factor also.

So figuring out the plate power input is a bit more difficult. The easiest thing to do, if that's what you want, is to estimate the difference from looking at tube data.

It's common to measure cathode current instead of plate current because that allows one side of the meter to be at or near ground potential. If the meter were in the high voltage circuit, it might create a safety or arcover hazard. I remember in the old days one would mount the plate current meter in an insulated fashion to avoid problems. It would, of course, look different that way. And it was downright dangerous to stick a screwdriver in to adjust the meter zero!

Hi all,

Ok, I have 42---3B7-3622 pot cores stacked, it is 18 inches long and 1
3/8"dia.
What can I learn about it as loop antenna and how should I go about it? I
have a
scope, and signal generator.
I don't think the material is to good over 400 or 500Khz.

Regards! I am a radio ham which is kind of "disconnected" I have not
been active for many years but I still have my license! I am an
engineering consultant in radio frequency and now that I am retired, I
am interested in the technology used for radio amateur.
My question! Does anybody know if cuircuits exist to automatically
generate the BFO frequency (Carrier Regeneration) for SSB detection in a
multiplier (or product detector); has any researcher tried to do that?
With today's synthesizers, is it possible to generate the IF frequency
with enough precision so that the SSB carrier regeneration (BFO) is
close enough for the audio to be comprehensible. Is automatic control of
the BFO a desired objective. How many hertz must the BFO be from the
suppressed carrier for intelligible audio? Thanks!
VE2AUC

3883. If output on TS440s

Hello,
I am wanting to use the SM220 + panadapter with my TS440 but it has no
IF output. Has any one made a mod to give if out on this rig ?
any helpful details appreciated.

also what is the bandwidth of the 45.05Mhz 1st if filter ?

Thanks Martin

I am a relativly new ham. I concentrate my operations from 50 MHz through 1.2 GHz. I have not had a lot of experience with older BFO type receivers. In my experience with modern synthesized receivers (Mostly ICOM), the synthesized VFO circuitry and product detectors are pretty much dead on and stable. Where I see improvement needed is in the area of Doppler correction when working satellites. I saw a recent article (QEX magazine?) about some software that worked with a computer sound card and was effective in automatically tuning and regenerating a clean SSB signal. If someone develops a receiver that can accomplish this quickly and repeatably in the DSP, it would be pretty attractive to those working the LEO satellites. It would be even more terrific if Timewave* or NIR would develop an aftermarket DSP that could do this. In my experience, being 50 or 100 HZ off frequency unacceptably reduces the intelligibility.

* How about it Timewave, a flash upgrade for the 599zx?

Wilbur, there's no doubt about it - any powdered form of magnetic material mixed with an insulating, non-magnetuc binder will have an extemely reduced effective permeability.

For example, solid iron has a permeability of the order 1000 or more. But when incorporated in iron-dust low-loss cores and toroids the permeability is reduced to 8 or 10. See the toroid manufacturer's data. With such a low permeabiliy rod you would be better off with a wooden dowel about four times the diameter.

I havn't done any calculations at LF but I would judge a 2 or 3-feet square, multi-turn loop or frame antenna, would be more sensitive and efficient than a solid ferrite rod antenna of the size you have in mind. Takes up a much larger volume of space, of course, but costs next to nothing.

Wouldn't take long to knock together an experimental square wooden-frame LF / VLF antenna. A twin-gang or 4-gang 500pF variable capacitor would be useful. Program RJELOOP3, available free from my website, will calculate the number of turns to wind on a given size frame, to resonate at a given frequency with a given value of tuning capacitor.

At 7 MHz the internal noise of an ordinary receiver is many dB below
the normal band noise.

So signal to noise ratio is determined by what is collected by the
antenna. Little can be done to improve matters except by increasing
antenna directivity and using a rotary beam.

The problem you describe cannot arise at 7 MHz. It is something to
consider at 145 MHz and certainly at 1 GHz.

It is a simple matter to check. Peak up the tuning on your receiver in
between signals and LISTEN only to background noise which is usually
very long distance static + local clicks and pops. Then disconnect the
antenna from the receiver input. If you like, terminate the receiver
input with 50 ohms.

If after disconnection there's a noticeable reduction in noise in the
speaker, despite the agc doing its best to keep it constant, then
there's nothing at all to worry about.

Even if the u of the rod changed from 500 to 5000, i doubt it would
make much of a change to a rod inductor, as most of the path is thru
air anyways...

<G4fgq.Regp@btinternet.com> wrote:

>At 7 MHz the internal noise of an ordinary receiver is many dB below
>the normal band noise.

"Ordinary" HF receivers have noise figures in the order of 10 .. 20 dB
without a preamplifier and the band noise at 7 MHz are 40 .. 60 dB
over thermal noise, depending on location and time of day and year. So
indeed, the reception is band noise limited.

However, consider a direct conversion receiver with a diode ring mixer
having a -6 dB gain (actually conversion loss) followed by an audio
amplifier with a noise figure of 10 dB (which may be typical for
amplifiers not designed with low noise as the primary goal). Due to
the loss in the mixer, the total noise figure would be 16 dB, quite
sufficient for 7 MHz. However, in direct conversion receivers, the
output is nearly DC and some mixers generate a strong 1/f noise, so
according to some articles in QST, the SBL-1 type mixer will exhibit
17 dB noise figures at audio frequencies, thus the total noise figure
is determined by the mixer noise figure alone.

Now, insert a 20 dB attenuator between the mixer and audio amplifier,
the combined noise figure will be -(-6 dB -20 dB)+10 dB or 36 dB,
which is close to the band noise for quiet locations. In this case the
mixer 1/f noise is much less than the combined noise figure of the
attenuator and audio amplifier and thus it is not included in the
calculation.

Terminating the mixer with a 50 ohm resistor and feeding the signal
into an amplifier with 5 kOhm input impedance has the same effect as
inserting a 20 dB attenuator between matched components.

>So signal to noise ratio is determined by what is collected by the
>antenna. Little can be done to improve matters except by increasing

>
>The problem you describe cannot arise at 7 MHz.

This is not a problem with a full sized dipole in urban areas, where
the band noise is very high, but can be significant in quiet rural
locations, especially if the antenna (and antenna tuner) is lossy,
which is often the case in portable operations.

>It is something to consider at 145 MHz and certainly at 1 GHz.

For 145 MHz I have usually seen noise values of 0 .. 10 dB over thermal noise quoted. For 1 GHz much lower values are quoted when the antenna is pointing at the "cold" sky.

>It is a simple matter to check. Peak up the tuning on your receiver in

Then repeat the experiment with all preamplifiers off and a 20 .. 30 dB antenna attenuator inserted between the antenna and receiver. This will much closely match the situation with mismatched audio amplifier.

The first amateur was Marconi in the history books but you
might want to check out Braun, Tesla, and a few others.

"Marconi shared his Nobel prize with German physicist Karl Ferdinand Braun, b. June 6,
1850, d.Apr. 20, 1918, in 1909 Nobel Prize for physics with
Guglielmo Marconi for his work in developing the radio.

Braun, who spent his career as a professor of physics at
German universities, increased the range of Marconi's
transmitter, invented the crystal rectifier (a device that
allows current to flow in only one direction, and improves
radio transmission), and later invented the oscilloscope, a
cathode-ray-tube laboratory device that was the forerunner of
today's television and radar tubes."

It sounds like you have the same problem I did years ago when building direct conversion receivers. I ended up with a common-base stage between the DBM and the main audio amplifier. The problem isn't so much matching the input impedance of the amplifier as it is putting the output from the DBM into a matched load that won't waste the signal and trash the noise figure. The common-base stage is biased at about 0.5 mA so you see about 50 ohms looking into the emitter. The collector and base voltages were derived from an "active decoupler" -- an emitter follower with well-filtered input -- to provide a very low noise source of voltage. This arrangement was first published in "An Optimized QRP Transceiver", in August 1980 QST, and was used in Hayward & Hayward's "Ugly Weekender" receiver in August 1981 QST, also by Rick Campbell in his R2 series of direct conversion receivers. One or another of these rigs have been in various editions of the ARRL Handbook over the years. I made a lot of noise figure measurements, and it came out quite respectable although I don't recall the value offhand after all these years. One thing -- If you do find the original article, don't use the 2N3565 I recommended. I later found out that its noise figure was terrible at that current, and that an ordinary 2N3904 and a number of other common transistors were much better.

For telephone speech quality reception, such as amateur SSB, the carrier should be re-injected within +/- 10 Hz, preferably +/- 5Hz. This requires a very long and short-term stable local master oscillator.

For broadcast quality and especially music it must be much better - within +/- 0.25Hz or better.

Thanks Roy for the advice. I did put a 50 ohm resistor across the terminals of the audio port and it helped considerably!! The noise came down, CW signals came up and strangely the broadcast band QRM went way down...this on 40m! I can plainly copy CW at 7.040. When I power down the VFO and leave the audio amp on the broadcast band interference comes back up?!?!

I'll look for the circuit you're talking about. I'm also considering a 741 op amp as a pre-amp but I'll have to find a relatively noiseless one. I also plan to build an active CW filter too.

The nice thing about it all is that the VFO is a module, the DBM is a module so it makes it easier to experiment.

I should say thanks here to everyone that's helped me!!!!

Happy Mother's Day Everyone.

I agree with Reg. Ferrite rod antennas are a good choice when volume is the primary consideration, as in a portable receiver with a built-in antenna. However, unless you have lots of bucks to spend on ferrites, an air-core loop is the way to go. There is a comparison of several portable homebrew LF receiving loops on my web site at http://www.computerpro.com/~lyle/listen/listn1.htm

The biggest ferrite rod antenna I've tried, which is about 30 inches long, is not nearly as good a receiving antenna as a 30-inch diameter "hula hoop" type of loop.

I have been looking for a solution to automatic tuning of SSB w/
suppressed carrier. It would help operate radios remotely via
the Internet. Right now network and audio encoding delays make
interactive ajustment of a receiver difficult. In services where
automatic tuning is important, the carrier is inserted in the
transmission (e.g., VSSB). If you know of a way for automatic
SSB tuning, I would be interested.

Using the chart in the Amidon Inc. book, of permeability versus
rod length to rod diameter, a 12 inch long .75 inch diameter rod
of #33 material with an initial permeability of 800 would have
an effective permeability of a little more than 100. A rod this
size, if available, would cost about 100 fine American dollars.

Richard Q. Marris, G2BZQ, writing in the March/April QEX describes
a low frequency loopstick antenna made from six ferrite
rods and a wooden dowel. The ferrite rods are glued together from
smaller pieces. This, probably, is not as expensive as one solid
rod, but it's still not cheap.

>

> next to nothing.

Marris mentions that the signal level using a 48X48 inch square
multiturn loop was greater than that of his ferrite core antenna,
but that the noise was greater also. A 48X48 box loop won't cost
anywhere near $100.00.

> ================================

Reg's advice is excellent. It would seem that the chief advantage of ferrite rod antennas is size reduction, an advantage for which one must be prepared to pay.

I would have thought that the start of Radio Astronomy came when Jansky
was working at Bell Laboratories from 1931(?) to 1935(?). To be fair,
Reber worked at home a couple of years after that and did a lot of good
work. Anyone know if Reber was a licenced Amateur or just a very good
SWL? ;-)

> 2) micro satellites

Probably one of the most significant examples (in my view anyway).

Mark.

Howdy Lyle:

I was hoping you would stop by and make a comment. My interest in ferrite loop antennas came from browsing through issues of the Lowdown. I was captivated by the 'Monster Loop' with a rod assembly 2.5" diameter and 216" long as described in April 1995 and the data on various loops presented in the in the December 1998 issue.

The interest I have is making my own rod out of bulk powder and epoxy. Like you said, the rods are expensive---especially from having to build a large core out of smaller lengths. I'm interested in making my own rods (or one large rod) out of bulk powder and epoxy. I was told this method was employed for short runs in an RF lab for evaluation purposes but I have no other information. They would get powder in sample bags about the size of a quart baggie, mix with epoxy then pour it into a mold, cure, whereupon it would it be tested electrically.

BTW, you are right about the high cost ferrite rods---why is this so anyway?

The TDA1072 or the TDA1572 have very good AGC characteristics, require no transformers at the IF input, and provide around 80dB of gain. The demodulated audio is so clean, that when I was demonstrating one of my radios to a fellow the other day, he thought I was using synchronous detection!

Somewhere in the dim past I've seen "recipes" for making your own ferrite powder -- I believe it was in a book about experimenting with magnetics, but can't remember any other details. Maybe there is an old Scientific American "Amateur Scientist" column that describes the technique.

> BTW, you are right about the high cost ferrite rods---why is this so
> anyway?

Beats the heck outa me. The price of ferrite rods seems to have risen at a pace that exceeds inflation. Must be supply and demand.

Kevin:

More Re: Marconi the amateur.

I have in front of me here a hard cover book "The wireless experimenter's manual", by Elmer E. Bucher, Wireless Press, Inc. 1920, LCCN 20-5750, LC Call Number TK9946.B85. In the back of the book is a tear out page which is an application form to join "The National Amateur Wireless Association", the fee for joining is $2.50. The address for the Association is given as 326 Broadway, Room 301, New York.

The head of this Amateur Association is listed as: Gugliemo Marconi, President
There is a National Advisory Board of Vice Presidents listed, which includes: Prof. Arthur E. Kennely, Harvard, Prof. Alfred N. Goldsmith, College of the City of New York, etc...

The text on the application reads... "Join Now" You should be a member of the organization that is doing real things for the advancement of amateur radio. etc.... I could make a xerox copy of the application form and fax it to you if you wish.

In recent years we have such "amateurs" as...

Phil Karn KA9Q...

who almost single handedly introduced the Internet's TCP/IP protocol suite to the modern personal computer [IBM clones as opposed to the Unix based computers] by the release of his "KA9Q" TCP/IP "stack" as free ware. Many professional programmers had said that the base PC with the 8086 microcomputer and 640 K of memory could never support such a complicated communications stack and that only powerful Unix machines could do that! Well... Phil did it anyway and then...

This KA9Q "stack" was picked up and modified by many commercial interests and led to the exponential growth of TCP/IP on the PC platform, and made a very large contribution to the commercial growth of the Internet.

it was an AFC circuit mentioned in Radcom 20 years ago, based on some
ideas for Collins 51-S or similar receiver. believe it was originally
described in QST, it uses AM envelope detector as well as product
detector. Once hooked it up on my 2m transceiver, but it was too
little and only random ssb activity for alignment, so I never got it
operational

Howdy.....confirm that the squelch will open....if it seems to work but level is still very low, inject audio at the volume pot to confirm audio amplifier basically ok. If this pans out, take another look at your tune-up....did you, by chance or purpose, adjust the discriminator so very narrow so as to not allow anything to be detected? I've made this mistake when I was green at it being fooled while using a CW source and not an FM source (all I had on hand). Other than that, perhaps an audio jumper out of place which may have formerly been used for comercial CTCSS etc. Best of luck.

Paul, your analysis makes sense. It's of value when the local
oscillator is noisy (which can be improved) and if the antenna in use,
such as a magloop, is 20 dB down relative to a 1/2-wave dipole.

I think automatic tuning of the local oscillator for receiving
suppressed carrier is impossible. There is nothing to lock on to. I
understand the few broadcasting stations which use SSB actually
transmit a low-level carrier for lock-on purposes at the receiver
which requires a phase discriminator.

What frequency range are you trying to test in and how accurate do you need to be ?

A simple way to test fundamental mode AT cut crystals is to simply use a chip like the National CGS3311

http://www.fairchildsemi.com/pf/CG/CGS3311.html

This will at least give you an approximate idea of what is going on. At the other end of the scale, well hold on to your wallet it can get pretty expensive.

Hope this helps.

Hi,

Unfortunately, filters for 10.7MHz are usually wider band, so strong
adjacent signals are let thru to the second mixer. So to get good
two-tone dynamic range, two high-level mixers are needed.

With a 455kHz single IF, i only need one ring mixer and less parts.

3921. Re: Ferrite Rods

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-15 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <8fnbpd$me9$1@uranium.btinternet.com>
Source record: 60576

The cost of ferrites lies in producing and controlling within close limits the various proportions of the long string of precise chemical compounds and clearing out the even longer string of deleterious substances. High pressures and high temperatures are involved.

The shaping and forming of ferrite materials is also an expensive process. They are diamond hard and brittle. Have you ever tried sawing a ferrite rod in half ? I have never yet succeeded even after ruining as many as three, cobalt and tungsten, high-speed steel, saw blades. The trick is to saw a notch all the way round the circumference and snap the beast in two. It occasionally works.

Any home-made mixtures, baked in the oven, poor-man's substitutes, are obviously entirely different materials. One might just as well experiment with iron filings and superglue.

Or wind some wire on a 6" diameter, air-core, pvc drain pipe.

3922. Ideas for a Homebrew Shortwave Receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-15 00:00:00 UTC
From: <antispam@clavin.freeserve.co.uk>
Message-ID: <8fnf5amne1@newsg4.svr.pol.co.uk>
Source record: 60577

Hi guys,

Im designing a SW receiver. The specs are... 5.95 mhz to 14.30 Mhz receive. Single conversion, 455 khz.

with... RF Pre-selector AND tuned RF amplifier to minimise 2nd order receive products. Switched 6dB attenuator for 3rd order product elimination. Diode ring mixer(low noise) followed by two tuned IF amp's sandwiching a murata CFG455H high performance 6khz I.F filter. Diode detector for AM and insertion osc/product detector for cw/ssb. SCAF audio filter and 3-4 watt audio output.

Anyone got any ideas to improve on things? For example, to minimise intermodulation products the VFO and insertion osc should be pure. Anyone got tips on how to design and build a spectrally "pure" oscillator? Also Which units should be individually screened when i begin to build?.. I'm thinking screened RF stage and screened VFO's. Any comments welcome....

Cheers, John. PS, how do I

3923. Re: Ideas for a Homebrew Shortwave Receiver

Source record: 60578

You might think about a higher IF frequency. Even a single pole crystal filter at say 30 or 40 MHz might help things some. 45 MHz cell phone IF filters go for a couple of dollars. I suspect you will have to do an image reject mixer to get rid of the IF image at 14 MHz.

On the VFO question most of what you see these days are microwave oscillators based on dielectric resonators. They divide them down to RF frequencies with low noise divider chips. Mini Circuits sells the VCO/divider modules fairly cheap. Look for the stuff with phase noise numbers in the -150 dbc/Hz region. Once you have one running you can run it through a tracking filter to clean it up some more.

Enjoy!

I do not know about speech, but music contains a lot of signals that have a rich harmonic contents e.g. 100 Hz fundamental with 200 Hz, 300 Hz, 400 Hz etc. harmonics. On SSB with +10 Hz error, these tones are at 110, 210, 310, 410 Hz etc. which are no longer harmonically related. Some DSP algorithm might try different frequency offsets in order to produce harmonically related output tones.

> I understand the few broadcasting stations which use SSB actually
>transmit a low-level carrier for lock-on purposes at the receiver
>which requires a phase discriminator.

The carrier is usually attenuated by 6 or 12 dB, significantly reducing the electric bill for the station :-).

It's interesting you mention the broadcast band QRM. If it doesn't change as you tune the receiver, it's due to AM demodulation. This is a real problem in direct conversion receivers, and can be minimized only if you have good mixer balance. One of the keys to this is proper mixer termination. Both Rick's and my articles talk about this issue, and the best mixer either of us has found for DC receivers is a diode ring.

Have a look at Rick Campbell's R2 DC Rx in the ARRL Handbook. He uses a
low-noise pre-amp with a diplexer. There are simpler circuits around
which are nearly as good.

The Analog Devices AD600, followed by the AD607 quadrature IF/demodulator chip is a good bet. Be advised, though, that it requires a fair amount of effort to get the '607 balanced for AM demodulation. I fiddled around with this combination about a year ago, and went to the TDA1072/1572 series of chips; I operated these devices at 455KHz though, so I didn't run into the gain-bandwidth issues.

The FREE internet video demonstrate just how simple and fast
the entire jigsaw puzzle manufacturing process can be.

If you have a slow Internet connection the first one would
be the best, and the third would be best for a fast
connection:

1. Low Resolution 320 x 240 video & sound :
http://members.home.net/puzzlemachine/POGI.rm
2. High Resolution slide show with sound:
http://members.home.net/puzzlemachine/Slide.rm
3. High Resolution video with sound :
http://members.home.net/puzzlemachine/POGIhi.rm

If you don't have the Real Player installed on your
computer, a FREE basic version may
be downloaded from this web page -
http://www.real.com/player/index.html?src=downloadr

4. Quick Time video :
http://members.home.net/jigsawpuzzle/POGI.mov

Profits that can be made from manufacturing jigsaw puzzles,
are broken down at
http://www.pacificcoast.net/~gciesek/profit.html

->chip is a good bet.

Nope. The 600 GBW is 3 dB down at 30 MHz. I don't know what it is like at 70,
but I tend to shy away from operating a device above the knee. Mostly, they
turn unstable in this domain.

AMEN! Then it does what I want, and ONLY what I want.

Next best thing: buy something older, like a TS820. Repairable,
rugged, built-in ps ,pi-net, and FSK, and a lot less than $1000. Take
the money you save and put it into good antenna materials.

That might be stretching it. I think MIT's PCIP predated the KA9Q software,
and probably had a larger base of commercial derivatives before CPU speeds
outgrew them.

But look at RFC 1122 for references to the "Karn algorithm" for computing
more accurate round trip time estimates for TCP. I think there is an
ACM SIGCOMM paper referred to in there. I'm pretty sure this came out of
the work with amateur radio TCP/IP (a lot of the really good, fundamental
insights into TCP protocol dynamics in the 1980's came from the experience
of running TCP over the really crappy networks that existed then).

fretman_2@my-deja.com wrote:

> BTW...what is spurious responses???

Dunno if someone might have already answered this in another sub-thread, but here goes:

Ideally, if you put in a local oscillator (LO) at 10.123MHz, that mixes 10.123MHz RF input to DC, and you hear 10.122 as a 1kHz tone, and also 10.124 as 1kHz, etc. And since 10.143 mixes to 20kHz, you don't hear that at all. And you don't hear anything else at, 'cept what's input between 10.103 and 10.143, spread out over the 20kHz audio range. Things beyond that are beyond your hearing.

But what actually happens is "higher order mixing products" -- a key one you'll hear about is "third order" products, and "third order intercept." So for example, if the input to your mixer (same LO as above) includes a strong signal on 10.500MHz and another strong signal on 10.880MHz, your mixer will put them together resulting in some (hopefully small) signal effectively at 10.500MHz minus (10.880-10.500) or 10.500-0.380 or 10.120MHz...and you hear a 4kHz tone because of that. Obviously, if those signals are modulated, you hear the modulation too. That's a spurious response...one that isn't supposed to be there but is. You can find lots of articles on what third-order intermodulation is and how to measure it. I'm sure there must be ones on the web. And you can find mixers with "third order intercept" points over a range from maybe a tenth of a milliwatt for inexpensive mixers (and/or ones trying to run on very low power) up to maybe a kilowatt...which does NOT mean you can put a kilowatt into the mixer! (Go look up the articles for more info. There's way more to the story than is appropriate to put in a news posting.) The higher the TOI, generally the less the mixer will be bothered by "out of band" signals.

Cheers,
Tom

> much better.

A couple years ago, I experimented with Roy's circuit, and found that a 2N2222 gave very good noise results, better than any other common NPN transistor I could get my hands on. PNPs typically have lower noise figures than NPNs but not lower voltage noise, from what I could determine, and it's voltage noise that's critical in this circuit.

But I also found that you can get just about as good a noise figure (and FAR lower distortion) using an op amp with really low noise such at the Analog Devices AD797. The '797 is undoubtedly better in the noise department than the 2N3565, and probably at least equal to the 2N3904, and only very slightly worse than the 2N2222s I tested. There are other less expensive audio op amps that have pretty respectably low voltage noise, too.

FWIW, I've never seen a reason to design the amplifier itself to have a low input impedance; the critical thing is that the amplifier have extremely low voltage noise, referred to its input. Whether the amplifier or an external resistor is the load seems irrelevant. But having a proper load on the mixer IS important, whether it's the amplifier stage or a resistor. And it's also a very good idea to have a filter to keep RF out of the audio amplifier input. Remember that the mixer output will generally include stuff from DC on up. I personally rather like the idea of a 50 ohm resistive load on the mixer, feeding into a singly terminated LC filter to kill the RF, that feeding the (low voltage noise but relatively high input impedance) audio amp input. (I gather from some Watkins-Johnson info that terminating the mixer into a short circuit for out-of-band signals is not necessarily a bad thing...but I'm sure no expert in that area.)

Cheers,
Tom

I'd sure agree that a transformer makes a lot of sense if you're going
to use something as noisy as a 741 (or the unspecified Radio Shack
amplifier). FWIW, Mouser (www.mouser.com) have a good selection of
inexpensive audio transformers. There's a 4.6k (ct) to 20 (ct) that
should work well, for only $1.73. I admit to a personal preference to
go the amplifier route with no transformers, but with parts with
seriously low voltage noise, which a 741 will simply never do.

Cheers,
Tom

3946. 2 transistor FM broadcast receiver - is it a joke?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-16 00:00:00 UTC
From: Peter Parker <parkerp@alphalink.com.au>
Message-ID: <39210a03@news.alphalink.com.au>
Source record: 60601

Published on page 300 of the April 2000 issue of Electronics World is a 2 transistor
FM broadcast receiver. It is not a super regenerative set. Instead the circuit claims
to be a synchronised oscillator that claims to recover the audio from FM broadcast
stations (direct conversion on FM???).

It is very simple - 2 transistors, 1 resistor, 1 capacitor and a tuned circuit. I have
never seen anything so simple for FM reception.

I couldn't get mine to oscillate or to receive signals. However given that it's the April
issue, I am open to the possibility that it could be an April Fool joke.

Has anyone built the circuit, and got it working?

73,

Summary: Buy Sell SWAP Ham Radio Electronics Computers 9AM - 2PM

This coming Sunday...

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday May 21st 2000
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23-W1BOS/R and W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)

I have figured out how to guarantee stability, and a garden-variety
BC548 works good.

The injection-locked oscillator will follow the fm of the strongest near-by
signal. Then you could feed the resulting strong fm osc signal into some kind
of discriminator. Haven't seen the article yet.

i have a Alinco DX 70t with the edx-2 auto tuner, I am running this in a 1991 Chevrolet Caprice v-8. The problem is ignition noise. Its been a problem with every radio install. My dads car, also a 1991 Caprice has the same problem. Were using resistor plugs. I need suggestions on how to rid the car of this noise, have one filter in line, still doesn't solve problem. noise is about 5-9 and s9 on am.
Has anybody else had these issues with the Caprice & or GM Cars? any help or advice appreciated.

You can 1) Use an LM2574 or similar voltage regulator as an inverter (see the Nat Semi web pages.) - it requires the IC, a couple caps, an MBR type diode and an inductor. The formulas to derive component values are on their website.

2) Check out the web pages of NatSemi, Tex Instruments (now includes Unitrode), Motorola (now ON Semiconductor) for flyback regulators - these require a transformer, but you know where to go from there.

As I remember Phil Karn introduced TCP/IP for amateur radio at one of
long gone Mid-Atlantic Packet Radio Council meetings.... (the one held
in Savage, MD). I can't put a year on it. But at the time the TNC-2 was
rumored but not yet a reality.

It was an amateur radio adaptation of the existing TCP/IP. Just as AX.25
was
an amateur radio utilization of the existing X.25 transfer protocol.

However, I think Phil did a lot of development for TCP/IP in his job
(memory wants to say that he worked for Bell but I may be wrong)

If I root around in the attic I might be able to find the diskette
he gave out that day.

But going on from here....
While packet radio was what we could call a "reverse" development in
amateur radio, meaning something we adapted, it sure did open the door
for commercial development of mobile data services.

I haven't had that experience with ham radios, however I did at one point get nasty ignition noise on the car stereo. I have a '75 Dart (V-8, of course), and what I did, is install
8.8mm Accel Spark Plug Racing wires. They're supposed to keep more of the electrical energy inside their heavier insulation, so you will have better RF suppression (and more juice getting to your plugs!) Hope it helps!

Try the TC7662B from Telcom (and others). It will invert 1.5v to 15 volts and it only uses two 10uF caps, no inductors needed. You can get it from digi-key.

I guess I was too brief. I'm putting together a 2 meter h-f transceiver/transverter station that will be for both portable (travel trailer) and home use.

Rather than two different setups, I want the low power (<100W) portion to run entirely on 12V. The home station runs an 8877 amp and antenna mounted Transco 24-28V relays (and I might use some more portable) so I need to manufacture an additional 12V. In addition, part of the sequencing will use negative bias back to the h-f transceiver ALC system to insure all of the relays are switched over before generating transmit power.

So, in my mind anyway, the simplest system is an additional -12V supply, stacked with the existing +12V to run the relays and supply the negative bias regulator.

I did follow the advice from an earlier post in this thread and
connected then disconnected the antenna. The noise went down to almost
nothing after disconnecing the antenna...so I believe the little audio
amp is probably doing a FB job. I'll get the notation off of the chip
in the amp and let you guys know what it is.

I sure appreciate the post from all of you and I'm learning alot.

There were sub-miniature tubes, though it's been a long time since I
saw any. They were glass, and had wire leads coming out one end. The
ones I'm thinking of had the leads in a straight line, but thinking about
it now, I thought thee were also some that had the leads in a circle.
Many or all of them had directly heated cathodes. I'm not sure what
made that design decision. I"m not sure what they were created for in
the first place, other than for miniaturization. I think they dated
before the space age, and may have seen use first in military applications.
In consumer items, they appeared in hearing aids, and some portable
radios.

Nuvistors were metal encased, and were about the diameter of a small
finger, maybe about the same height as to the first joint. It's been
a while, but I remember them having leads in an odd pattern. A mini-DIN
connector (like you see on Macintosh computers) reminds me of about
the size and lead arrangement.

I saw the circuit (and for others, it's not an article but a schematic
and a very brief description), but didn't buy the magazine. It did
remind me of a circuit I saw in Elektor years ago, which I can't put
my hands on at the moment. I've seen mention of the idea somewhere.
So whether or not that particular circuit works, the idea supposedly
is sound.

I once saw the book put about by Collins (and later reprinted by
Ham Radio magazine) about SSB, and I seem to recall something in
there about AFC for SSB. Someone who has the book might want to
check because I remember none of the details.

About 1964, there was an article in 73 about AFC for SSB and it
used a discriminator. It didn't quite explain how it worked, and in
the end, I think it was based on a leaky carrier, which at that
time might have been a more common occurance than nowadays.

Of course, as we've gone through here before, a DSB signal with
suppressed carrier includes information for placing the carrier
right in the required place. That begs the question, which is
a better tradeoff? A weak carrier sent along for the purposes
of locking the BFO, or sending two sidebands without a carrier?

Does anyone have the mods for Standard C178S to allow additional frequencies
to be covered?

Thanx

Richard

3969. FS: Rf comps for builders (long)

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-16 00:00:00 UTC
From: Brad Thompson <brad.thompson@valley.net>
Message-ID: <3921A1C1.C8796614@valley.net>
Source record: 60624

Hello-- Revised -05/16/2000

I'm offering homebrew builders the following NOS (new old stock) RF components, including...
***
Hewlett-Packard MSA-0786 MMICs ($1.00 each, $5.00 for 6, $10.00 for 15, or $25.00 for 50 pieces); DC-2 GHz. These are taped and reeled and have leads configured for surface-mounted applications.

Specs are available at HP's web site (or with your order)...

http://www.hp.com/HP-COMP/index.html
***
1N5453B Variable-capacitance diodes, full-length leads, taped and reeled. Nominal capacitance of 56 pf and Q of 200 at 50MHz and 4 VDC. $1.00 for 3 pieces.
***
1N5711 Schottky diodes, full-length leads, taped and reeled, $1.00 for 10
pieces
***
1N5817 Schottky rectifiers, full-length leads, taped and reeled, $1.00 for 10 pieces
***
1N5821 Schottky rectifiers, full-length leads, bulk packed, $1.00 for 8 pieces
***
PIN diodes, no specs available; full-length axial-leaded packages; individually serialized in sealed-foil envelopes. $1.00 each.
***
JAN 1N748A Zener diodes: individually sealed in mil-spec foil packets for your protection<g> in 1983.
$1.00 for 6 pieces.
***
SD-201 Signetics DC-2 GHz DMOS single-gate FETs four-lead TO-72 can (like TO-18 w/shield lead). A conductive-rubber antistatic "O" ring encircles
all four leads. Specs (available on request and with purchase) include S parameter plots. $1.00 each, $3.00 for 6, $5.00 for 12 pieces.
***
TN-2219A National Semiconductor NPN general-purpose NPN transistor: 100 < hFE < 300 at Ic= 150 mA; BVcbo = 75 V min.; BVceo = 40 V min.; Icbo = 10 nA max. at Vcb= 60 V; Cob = 8 pf max.; Ft = 60 MHz min. at Ic = 20 mA. NF 4 dB (max.)
In TO-237 metal-tabbed plastic package (similar to TO-92); this package

reduces thermal resistance from 125 C per watt for a TO-92 to 50 C per watt for the TO-237. Ideal for building a QRP rig around a single device!

$1.00 for 20 pieces; $5.00 for 120 pieces
***
Minicircuits T1-1T (1:1 turns ratio (center-tapped)) broadband RF transformers (80 KHz to 200 MHz); leads are formed for surface mounting but you can rebend for DIP insertion. Visit www.minicircuits.com for full specs via their catalog.
$2.00 for 3 pieces
***
Minicircuits PSCQ-2-400 90-degree, 2-way power divider, 0.9 dB insertion

loss, 225-400 MHz; $1.00 each
***
Fair-Rite cores (both type 43 mix):

2643023002 (a long-cored toroid) $1.00 for 10 pieces
2843002402 (binocular (balun) core) $1.00 for 20 pieces
***
Coilcraft p/n 142-07J08 single-winding adjustable inductors.
330 nH min./ 378 nH nom. /427 nH max.; 307 nH with tuning slug removed. Q is 112 min. at 40 MHz; 7.5 turn winding on 10 mm molded form.

$1.00 for 5 pieces; $5.00 for 35 pieces.
***
Chip Inductors: Coilcraft 1008CS family-- 10 by 8 mils, ceramic construction. Full specs are available at www.coilcraft.com

Coilcraft 1008CS-270XMBC 27 nH +/- 20 percent
Coilcraft 1008CS-470XMBC 47 nH +/- 20 percent

Coilcraft 1008CS-680XKBC; 68 nanohenry, +/- 10 percent, Q(min)=65 @ 350 MHz, self-resonant frequency of 1300 MHz minimum, Rdc = 0.2 ohms max., 1 ampere DC max.

Coilcraft 1008CS-332XKBC 3300 nH +/- 10 percent

$1.00 for 8 pieces of one value or any mixture of values

***
RF power xfmr.: consists of two 1.125-inch long by 0.570 inch OD type 43 ferrite sleeves with tubing primaries. Two small circuit boards short one end of the tubes, and the other two are not connected.

A section of Teflon (tm)-insulated wire passes through both tubes' centers twice, making a 1:2 turns ratio (1:4 impedance) stepup transformer (you can easily remove this winding and replace it with more turns of smaller gauge) At a (nonguaranteed) guess, the assembly might handle 100 watts of RF. The cores are .

Price: $1.50 each (scanned image available on request)

***
Pulse Engineering PE-53190 toroidal inductor for switched-mode power
supplies.
Inductance = 12.2 microhenries at zero DC; 8.7 microhenries at 2.5 A DC.

Price: $1.00 for 6
***
SAW-stabilized oscillators; intended for ECL circuits, but also
reportedly usable as LOs. All are packaged in metal DIP cans.
$4.00 each, or three assorted for $10.00

Frequencies available are:
222.222 MHz (RF Monolithics HC1279; proprietary p/n marking)
350.000 MHZ (RF Monolithics HC1301)
366.667 MHz
400.000 MHz ($2.00 ea. but NOT NOS; removed from PC boards)
733.333 MHz
***
Teflon- and diallyl-pthalate insulated single-point turret lugs at
$12.00 per 100 (many styles available-- e-mail for information and a
jpg image showing various types).
***
Global Specialties Experimentor (tm) PC board EXP-300PC; use one
of GS' solderless breadboards to rough out your circuit, and then
build a final copy on one of these PC boards. $1.00 each, NOS in
carded shrinkwrap package.
***
Feedthrough capacitors: Spectrum Control 100 pf nominal (threaded
bushing mount, hardware included). Attenuation is specified as
-10 dB at 300 MHz, and -20 dB at 1 GHz.
$.50 each, $1.00 for 3 pieces. ***ONLY 32 PIECES REMAINING***
***
Air-variable capacitors manufactured by Cardwell (their part no.
PL6348).
NOS surplus, m'fd. sometime in the 1950s.
--Configuration: consists of two plates separated by 0.1";
--Estimated capacitance range: 1-5 pf.
The adjustment shaft is 0.25" dia. by 0.5 inches long; bushing or
isolated mounting; easily disassembled for capacitance vs. frequency
modification, etc. A more-detailed description is available on request.

Price: $1.00 each, $10.00 for 12 pieces
***
Caddock MS281N NONINDUCTIVE resistors:

10 ohm +/- 5 per cent tolerance, 8 watt noninductive power film
resistors
Tinned axial leads (0.75 inches long) are formed for PC-board
insertion on 1.2-inch centers. These are NOS, bulk-packed parts.
Note: these measure well within tolerance at +/- 0.2 ohms typical. Full
specs are available in PDF format on Caddock's web site
(www.caddock.com)

but highlights are:
--Temperature coefficient of resistance: 50 ppm;
--Power rating: 8 watts at 25 C, derating to 4 watts at 150 C and
0 watts at 275 C;
--Noninductive design: serpentine film layout cancels magnetic field-
equivalent inductance of a straight piece of wire of the
resistor's body plus lead length.

Applications include:
--Current sampling;
--Cathode bias;
--Dummy loads for audio and RF applications.

Price: $1.00 each ($10.00 for 12 pieces); only 50 pieces available
****

So many questions! Here's what I can pass along: Somewhere along the way, you need a reference to lock on to if you don't want any frequency offsets in SSB.

Some have used a technique known as ACSSB. I don't remember exactly what the letters stood for. It may have been Amplitude Compandered Single Sideband. It used a pilot tone to establish an AGC and frequency reference. The only problem with this method is the similar to what one would find on Shortwave AM broadcasts. If selective fading hits the pilot tone, you're screwed.

ACSSB used the reference to steer the BFO so that it was on frequency for the incoming signal.

Another method used DSB with suppressed carriers. Look up the Costas Loop circuit if you want to know how most ICs and high performance circuits do this. This arrangement is a bit more durable than AM during severe cases of selective fading.

However there is an even easier system available to almost anyone these days. If your receiver has the ability to accept a frequency reference (and many do), then get a frequency reference from a common source such as WWVB or even a GPS based atomic standard. These standards are extremely accurate. Once you're locked on, you'll know your frequency to an accuracy of less than one cycle per second. If you coordinate with other stations in advance, you'll be exactly on frequency without having to send any extra synchronization information.

Those are just a few ideas. Once you start investigating, I'm sure you'll think of others...

Hello and thanks in advance from a beginner.

I wanted to know how inexpensively one could buy or build a receiver (for any frequency), even a single frequency receiver.

I have limited experience with electronics but I do okay.

Thanks again.

Regarding ignition noise, it is hard to diagnose from a distance, but I'll try to give a pointer or two. I think it is unusual to have much ignition noise from a GM car, but it does happen with all vehicles from time to time.

1. Run all power leads direct to the battery.

2. Check all installation issues (antenna mount, coax for bad connect-ions, etc.

3. Ground the radio via shortest route to frame/body.

4. Make sure that the body has good ground to frame--might even run gnd straps to frame at both ends.

5. Make certain antenna mount is grounded/installed correctly.

6. Ground hood and trunk on both sides near the hinges.

7. Ground muffler(s) with braided straps to frame. (Welds often do not provide a good RF ground.

8. Remove antenna and see if noise is still present with whip off. If it is, it is RADIATED noise.

9. If it is radiated noise, then you have to find what is radiating the noise to the antenna. I once found that ignition noise was following the taillight harness back to the light bulbs and radiating the noise onto the antenna. So remove the light bulbs in the taillights and seeif it stops.

10. I have never seen any inline filter remove ignition noise. So in-stall caps across the alternator (for whine), and across the power leads for electric fuel pump (if any).

11. How long has it been since the plug wires were replaced?

These are just some of the things you can do to stop the noise. It may be something simple, or it may be hard to trace. Chevrolets are usually not very noisy, so I tend to think there is something amiss with the electrical system (plugs, wires, etc), or the rig/antenna is not in-stalled properly.

Good Luck,

Jerry

I was told by a Ham friend to investigate "Electronics & wireless world"
year 1970 and September issue of 1989. I am wondering if a reader of this
news group has these issues.
In any way I am going to contact the University library to see if they have
it. In the meantime, I would be interested by anyone having information on
the Analog Devices
DSP board which has a BFO, to see if the device can tune automatically or if
the operator "ear" is still neceaasary as the AFC. Regards!

Hi Dan (and lurkers),

You bring back old memories. I got started in ham radio in a place where a lot of the kids had way less than I did, and I didn't have all that much. But one of the fellows who got his license when I got mine did quite well with some home-made equipment. He talked (on CW) 3000 miles across the country with a very simple transmitter and receiver. The receiver was a regenerative set with one or two tubes. We used to get parts from scrapped TV sets and radios. You can do the same sort of thing now with transistors. I'd be surprised if you couldn't get all the parts you need for free. If you were nearby, I'd gladly give you old boards with plenty of parts to do everything you need, except perhaps tuning capacitors, but hey, I'd even throw in something you could use for that if you were serious. I'll bet you can find 'lectronics 'sperimenters and the like in your area that will give you all sorts of stuff.

I've listened to broadcast stations from about 1000 miles away at night with a "crystal set." OK, I cheat: my "crystal" is a semiconductor diode, and I follow that with a simple audio amplifier. But you can learn a lot from something so simple: you can learn about tuned circuits and how to make high Q coils to keep losses low but still reject local stations.

There are web sites with all sorts of simple receiver ideas. I'm sure others will post some pointers for you, or you can just do a web search.

Cheers,
Tom

WA2FSO,
First, lets find out if your getting the noise through
the power lead, or the antenna. To do this, while the car
is running, and your hearing the noise, disconnect the
antenna. If you still hear the noise, it's comming through
the power lead. If the noise disapears, it's comming in
through the antenna.
While plug wires may make a difference, they aren't the
only source of noise by any means. The same methods of
getting rid of noise always apply; shield, by-pass, and a
five gallon bucket of torriods. '91 usually doesn't have
a fuel pump in the tank, but it can have an electric fuel
pump. If so, by pass it with a capacitor. Try grounding
the motor block to the chassis, body panels to the chassis,
the radio/antenna to the chassis. Everything you can think
of to the chassis. The individual body panels, etc, will
make a small difference, but they are all accumulative. The
'total' can make a big difference.
One note on grounding straps. 'Braid' works fine when
it's first applied. Over a period of time, it will deteriorate
and the 'ground' will suffer. I'm not talking about tarnishing,
I mean that the weather/polutants/etc will make it 'rot'
away. Use a metal strap, such as copper flashing used around
chimneys etc. The bigger the better, within reason.
Good luck.......
'Doc
PS - By-passing the power lead, etc, is never a bad idea.

Daniel,
That depends on what you may have in your 'junk-box'.
It's possible to build a very simple reciever for zero
dollars, and then again, it can cost a lot more than
buying a new one.
If your very close to a broadcast station, a diode
and a set of earphones will/can receive it....
'Doc

I have a '91 GMC 1500 truck that probably has the same hardware as your Caprice. I get lots of noise off of the spark plug wires. I've found that replacing the cap, rotor, plugs and all the plug wires including the coil wire about every 50,000 miles helps keep the noise down. It also helps to clean the contacts on the spark plug wires periodically, especially the end that goes in the distributor cap and ignition coil because they get white powdery deposits that will create a spark gap. If your car is like my truck it has a separate ignition coil. Make sure to clean both ends of that coil wire. I found that the dealer had neglected to do so and I got an incredible noise on the radios. That high energy ignition will force a spark through an awful lot of crud to keep the engine running and create a lot of RF noise while doing it.

3978. Key ON ignition noise 1990 Chev Suburban

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-16 00:00:00 UTC
From: arronenglish <aenglish15@hotmail.com>
Message-ID: <392205e2_3@127.0.0.1>
Source record: 60633

I have a 1990 Chev Suburban w/ 350 cid gas engine. I have a horrid, relatively high-pitched "raspy" noise evident whenever the ignition switch is in the ON position. No need for the engine to be running. It is entering my mobile rig via antenna connection, not power leads. The noise is most evident on 20 meters, but is not much diminished on any other band -- it is impossible to use the radio as a mobile for *any* non-FM purpose.
I presume the noise is being generated by either the vehicle "computer" (such as it is in a 1990 vehicle) or the electric fuel pump.
There are two bundles of wires connected to the computer module; I put a 1" long ferrite clamp (RadioShack part) on those bundles today and noted no difference in the noise.
I've tried to find the fuse to the fuel pump so that I can disconnect it to see if that stops the noise, but no luck there yet. I do not have access to a service manual to help in finding on which fuse circuit the fuel pump lies (I presume the pump is inside the fuel tank, but that is guarded by a skid plate).
Any suggestions other than 1) sequentially pulling every fuse in the panel whilst listening to the radio, or 2) disconnecting all wires from the computer module?
Thanks in advance,
Aaron

The simplest receiver is a diode detector. Originally known as a crystal set. Requires no batteries or transistors or tubes. Only receives AM. See any tutorial on receivers for diagrams; it's so simple it doesn't take much at all.

On the other hand, if you want control over bandwidth, or want to receive other types of modulation, better sensitivity, more audio output, and so on, you have to add cirrcuitry and the cost climbs.

Howdy Aaron.....To confirm fuel pump is the culprit, note whether the noise is heard immediately after switching ignition ON (but truck not cranked) for approximately 2 seconds after which time it disappears unless the engine is cranked and runs then - it will show up again. This 2 second run cycle is used for priming the system prior to starting (many people don't know this and merely crank through the time until it starts). Now, having said this, I also remember reading in various packet BBS over the years of some success tracking one source of GM noise down to a device called the DRA (digital ratio adapter) located at the rear of the instrument cluster. This is a configurable device used to make the computer and sometimes the cluster (if electronic) "see" the correction for various driveline final drive ratios. I've checked my files but can't find it right now. Best of Luck.

Aaron,
I once tracked down a really nasty noise in a car by winding a coil of wire (about 10 turns and 1 to 2 inches in diameter) and connecting it to the end of a coax cable supported by a plastic rod. This device was described in the ARRL Handbook. Connect the coax to your radio then wave the coil around over potentially offensive devices on the car. In my case it turned out to be the fuel injection control module which was in a plastic enclosure. Wrapping it in aluminum foil and connecting the foil to the chassis helped. I made sure to open up all ventillation slots. The noise was still there but it went from 20db over 9 to about S7 on 20 meters. Eventually I pretty much gave up on 20 meters and went to 17. The noise was not present on that band. Good luck

My experence is with my 87 Suburban. The HEI ignition is a killer and my first rig, a DX70, had virtually no noise blanker whether in the mobil or out. So I traded off and put a 706MKII in my Suburban. Ignition noise still a problem until I got the Magnacore wires. Now that helped a bunch. I did all the grounding, etc and cleaning you could imagine. I run the 706 with a Bandhopper screwdriver antenna and use a Ten Tec amp. So far my HF mobil ops are really fun.

I started building ham gear last year so I'm kind of where your at experience wise. However I've had some time to look and see what is out there.

I just built the Ten-Tec 1253 9 band receiver last month. It cost $59.00 (+ s.h.). Its a regeny but it works pretty well. The selectivity leaves something to be desired but..... I built it to use while I got my tube based superhet built.

The gear I build uses tubes for two reasons. One, I got a lot of them that I collected as a kid that were still in a box in my folk's basement (after 25 years). And because they're so damn neat.

If your on a limited budget like I am, tubes can be the way to go. The superhet that I'm building is costing me only a few dollars, mostly for the transformers. I got most of the parts that I needed from some old junk tube radios that I got for a buck from a second hand shop.

If your looking for something fairly easy to build without a lot of cost, look into the kits offered by Ten Tec, Ramsey, and others. Kits are a good mix of cost, perfomance, and simple construction trade offs.

If your interest, e-mail me and I'll point you in some directions to start (may not be the right direction but still..). Good luck

Oh, a challenge! I'll bet I can receive FM on one... Of course, I DO need to add some tuned circuits, or at least one tuned circuit. But for sure there's no reason I couldn't build a ratio detector with just diodes and tuned circuits, tuned directly to an FM station. And slope detection is even simpler. Stereo might be a bit tough, though. ;-)

Best to begin with the most simple and inexpensive arrangement
possible.

The most simple receiver is for the medium-wave AM band. All you need
is a coil wound on a toilet roll tube, a 350 pF variable capacitor, a
germanium diode and 150 feet of 20 gauge magnet wire. Half the wire
will be on the tuning coil and the other half ouside in your back
yard. Use your domestic metal cold water pipes as a ground
connection.

Because a pair of sensitive high impedance, 4000 ohms, headphones are
very expensive even if you knew where to get any (you cannot have
mine) you will need a single-chip, 200 mW, audio power amplifier and a
small, 2" 8 or 16 ohm loud speaker. Or a hearing aid insert.

Put a small soldering iron and reel of cored solder on your shopping
list.

When that job's done you will be well on the way to becoming a fully
fledged radio amateur.

perhaps it is an idea to use the available transformer whatever it is,
and change the circuit to suit this? If a 100 to 1000 ohm transformer
is available it may probably work as 50 to 500 ohm for a limited
frequency range

If you take Bill Kane's advice and give up on the Chevy, consider a Ford
with the 460 engine. I have a '96 F-250 pickup that I can operate HF mobile
in WITHOUT THE NOISE BLANKER. It really is that quiet, believe it or not.
I have been HF mobiling for almost 40 years in all kind of vehicles and have
never seen anything as quiet. YMMV, of course, so take a shortwave receiver
with you when you go car shopping and try to ignore the puzzled looks from
the salesman.

Well, for the fun of it I built a small 80M CW receiver, transmitter, and telegraph key for about 10 bucks in the hardware store plus some minor parts scrounging. It is crude, but it works. One can do a lot if one scrounges and thinks a little about it, and is good at adapting the flotsam and jetsam of the electronics world to make the critter.

http://www.mindspring.com/~johnmb/na4g2.htm

Not necessarily recommended for contesting, but great for a little fun on 80M, in the evenings.

Good Luck, and have fun building.... that is a lot of the fun of Amateur Radio.....

I have a 97 GMC Suburban, and have reduced the ignition noise somewhat. Here's what I did: bonding of all metal parts that i thought were not adequately "connected" to the frame, MAGNECOR 8mm wires, new plugs, rotor, and cap. Also found a tech service bulletin at the "ALLDATA" site that addressed noise in mobile radios.The dealer can reprogram the engine control computer in my GMC to reduce ignition noise. It worked.
Good Luck

Dear OM

I have read the postings here advising you of what to do. Its all good advice. Unfortunately I had a Chevrolet Caprice 1987 with the same problem as you and never was able to curb the ignition noise, maybe a couple of db's that was it. My 706's blanker made no difference, in fact it was overwhelmed.

I did all the things the others have advised and then some with no satisfactory results. I even went so far as to buy an ANC-4 noise eliminator and put a sense antenna directly into the engine compartment and tried to phase the noise out but to no avail. Just a waste of $160.

I even questioned the General Motors engineers who show up at Dayton every year in a special booth inside and they did not know what to tell me. Every solution they suggested I had performed with negative results.

I tell you this to help you avoid going through a very frustrating experience. These GM cars pump out 40kv spikes that no kind of suppression, even digital, can cure. Bad design or what, I don't know and no longer care. I would set my sites on getting another vehicle down the road and assure myself it is inherently quiet. As for me, I mobile as a portable on HF. As soon as I start the engine and begin to move I turn the rig off so my blood pressure dosen't begin to boil.

The only vehicle I ever had that I could HF mobile in was a diesel. Do yourself a favor and give up on the Chevy. Sorry to be negative but that is my advice to you.

Ok,
For once the TV is interfering with my DX work, rather the the ham radio interfering with the TV.
When working DX on 20m or below, when ever the TV is on, it acts as a signal generator every 15khz(always on to of the rare DX) through the HF bands. If anyone knows out how to eliminate or reduce the interference please e-mail me at:
aa1uz@arrl.net.

Thanks and 73,
Drew Leavitt,

All TV sets have a 15 kHz transmitter built in. It's called the horizontal output stage. Even worse, tv's have almost no shielding, and are in plastic cabinets so the signal is free to radiate. You can try to reduce the interference by using a power line RFI filter at the ham rig and also at the TV set. There have been construction articles of these in ham handbooks and magazines. Relocating the TV set may not be practical, but that can help also.

My favorite is PVC pipe. You can easily cut it lengthwise
and create nice strong end insulators. I also use them
for spreaders on home made open wire line.

Take a look at the following article. The author makes
good use of PVC spreaders and insulators.

http://www.natworld.com/ars/pages/back_issues/0698_text/ffd.html

I�m no HF expert, but I recently noticed that standard AM IF
transformer cans have one hell of a selection if used "backwards"
(tapped side as output, but not using tap) and driven from a high
impedance source (10-500K resistor) combined with a high impedance on
the output
(I used 33pf coupling to next transistor).

Source record: 60445

The shielding is usually done so there is inductive coupling only and no capacitive coupling. Sometimes makes it easier to ensure the coupling is only by the desired method and ammount.

To get the selectivity needed you can over couple the coils, or you can stagger tune them. There are 3 types of coupling--under, critical, over. Under coupling will not transfer the maximum power, critical will pass the maximum power and not make the passband much wider, over coupling will make the passband broader.

> At the output of the rf amp, there is a "bandpass filter" to couple the

Back in the mid 60's I maintained a VHF/UHF doppler DF unit for the FAA in Bakersfield. This unit had 16 antennas and as I recall the bearing accuracy was around 2-3 degrees. So the answer to your question is 'yes'. However of course, the circuit has to be designed to accomodate the number of antennas used.

4025. Cell Phone Conversion

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-19 00:00:00 UTC
From: George Andrews <mauser2@erols.com>
Message-ID: <8g5jod$ek4$1@bob.news.rcn.net>
Source record: 60451

To All,
Has anyone converted a portable cell phone to the 900 MHz amateur band? Is this in fact possible? My thanks in advance to all who respond.

4026. Live voice & text chat for hams

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-19 00:00:00 UTC
From: MITBR <mitbr@earthlink.net>
Message-ID: <Vx%U4.2631$S31.44623@newsread2.prod.itd.earthlink.net>
Source record: 60524
Cross-posted to: nl.radio.amateur,rec.radio.amateur.boatanchors,rec.radio.amateur.digital.misc,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.space,rec.radio.shortwave,tw.bbs.rec.radio.amateur

Hello folks!!
Just wanted to let everyone know that there has been major improvements to
the world wide voice & Text chat system for hams!! There is now the
provision for private chat rooms. The idea is that you wait for someone to
arrive in the main chat then go to a private chat with them if you wish. The
audio in the system rivals that of anything currently available and also
supports a text chat on the same screen. Use the system to set up skeds,
check the muf on a freq, meet new hams, have meetings or just plain ragchew.
Go to the url here to directly enter the chat
http://home.earthlink.net/~mitbr/AmateurRadioChat.htm
If no ones there when you arrive simply hang around for awhile while you
surf the net some one will come along!! Spread the word folks .

I did measurements on a set of these 455kHz cans: red, white, and
black ones. The red is the autodyne converter, white is for intermediate
IF stages, and black drives the envelope detector. The white and black
ones had an unloaded Q= 30.

No I want to change channel 1 from 145.000MHz to another frequency. I know how to delete channels but I can not delete or change channel 1. There is a note on page 35 of the manual that states "Note that memory channel 1 may not be deleted, as it is the priority channel." I can't seem to figure it out.

Hello,

I have the following items for sale. Please note, the prices do not include shipping.

73, Joel KB7RYU (Phoenix, Arizona)

World Radio Laboratories Map dated 1960 - Like new condition $5.00

Radio Handbook Fourteenth Edition 1956 - Good condition $15.00

Radio Handbook Twelfth Edition 1949 - Like New $20.00

Radio Handbook Tenth Edition 1946 - Has a "" tear along top right side of spine, otherwise good condition. $20.00

Radio Circuit Hints - Volume One Compiled and Published by Sylvania Electric Products Inc. 1943 First Edition Fourth Printing Excellent condition $5.00

Radio Tube Hints - Volume One Compiled and Published by Sylvania Electric Products Inc. 1943 First Edition Fourth Printing Excellent condition $5.00

Radio Equipment Hints - Volume One Compiled and Published by Sylvania Electric Products Inc. 1943 First Edition Fourth Printing Excellent condition $5.00

Radio and Television News June 1955 Good condition with exception of slight tear at bottom of spine. $1.00

Popular Electronics June 1958 Slightly yellowed and has a callsign written on cover - otherwise looks good. $0.50

I tried to describe and price the following QSTs as accurately as possible. If anyone has a question as to a specific issue etc., please email me (azkb7ryu@aztec.asu.edu).

July 1948 Fair to good $1.00
Sept 1948 Fair to good $1.00
Nov 1948 Fair - Edge of cover is a bit worn but not bad. $1.00

Dec 1952 Fair $1.00

I have a Sorensen power supply. Not sure, must be late 60's or early
70's. It has 4 2N441 germanium power transistors in its output. A
reference manual from 1973 rates them at IC of 15A. I have thought some
about if its worth fixing if the output stages ever fail, but so far no
need to actually worry about it. Germanium has plenty of drawbacks, but
the transistors of the early era can't be too bad if they are still
working ok.

I have no idea about the actual construction of these transistors.

Be a little careful here. Some PVC has a rather high absorption of
RF fields, which can result in excessive heating of the PVC (and,
thus, softening of it). I seem to remember that it has to do with
some particular chemical properties of the PVC sample in question,
and thus some PVC will work fine in high RF fields, while other PVC
will (over-)heat and melt.

You might try doing a web-search, but I seem to remember that one person advocated inserting a small sample of the PVC that was to be used for an antenna project in a microwave oven (along with a suitable ballast load so that the oven wouldn't blow itself up), and measuring the temperature rise of the sample. Do the web-search for the exact details of the test arrangement, though, before trying it (Flaming PVC in your microwave may be hazardous to your health, especially if your wife finds out!). :*)

Dave

P.S. Standard Disclaimer: I work for them, but I don't speak for them.

> Mark Zenier mzenier@eskimo.com mzenier@netcom.com Washington State resident

Maybe as much as a decade ago, I saw somewhere a reference that Fox made
crystal filters. Knowing that a cheap source would be wonderful for
homebrewers, I wrote away for a catalog. I may still have the catalog,
but I remember none of the details. However, there were no prices mentioned.
So I wrote them again, asking for a price list. Fox wrote back saying
the information was "proprietary" (I'm certain they used that word). So
I abondoned that project.

My interest in them was as a potential source of cheap crystal filters.
But if they couldn't be bothered giving me an idea of what the price range
might be, then there was no sense in telling the ham world that they
were a source of filters, which had been my intention when I sent away
for the catalog.

I can't remember if any of the filters they made were narrow. Those center
frequencies certainly are common for narrow band FM, so I'd tend to
believe that they are on the wide side. Useful for some things, but
not if we are talking single conversion SSB or CW receivers.

Digi-Key lists some NBFM crystal filters (at 10.7MHz) in their catalog.
There is a small selection of bandwidths and number of poles. (And they
also list some 455KHz filters of more suitable bandwidth but ultimately
I'm not sure they are narrow enough or have good enough skirt selectivity
for SSB and CW use.)

FM-bandwidth filters are relatively easy to find. You are far more likely
to bump into a NBFM receiver than an SSB receiver. So you can find all
kinds of scrap equipment for extracting such filters, and even buy them
easily from suppliers such as Digi-key or surplus outlets.

It's finding those cheap SSB/CW bandwidth filters that is difficult.

Michael VE2BVW

4036. basic ?? about rcvr front-end filters

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-19 00:00:00 UTC
From: JGinNY <jwg6@cornell.edu>
Message-ID: <392584CB.35664F7D@cornell.edu>
Source record: 60534

This question regards bandpass filtering following a receiver's rf amp.

Say you have a simple HF or VHF superhet receiver circuit, with an rf-amp stage boosting incoming signals.
At the output of the rf amp, there is a "bandpass filter" to couple the rf to the next stage (the mixer). This bandpass filter consists of two slug-tuned inductors, which are to be adjusted so they resonate at the desired frequency band.

Question: in reviewing some construction projects in the handbooks, I see that often, the two inductors of the bandpass circuit are separated by a metal plate or shield. Why is this? Does the coupling need to be restricted to such a very low amount? In one particular circuit, the two coils are wound at opposite ends of a slug tuned form, about 1/4" diameter and maybe 2.5 inches long. The coil form is installed vertically, through an appropriate hole punched in the chassis, so that one of the coils is situated above the main surface of the chassis, and the other coil is below it. Since in the schematic, both inductances are shown as adjustable, my guess is that there are two slugs in the coil form, one for each winding, with one being adjusted from the top of the form, and the other being adjusted from below. Sound likely?

Why the shielding (chassis or metal plate) between the inductors? Or in other words, what extent of coupling between the rf amp and mixer is sought? (Evidently not much...?)

On a similar note, how is a fairly broad band-pass achieved, so that the signals over an entire ham band will be passed without undesired attenuation? Does this have to do with loose coupling afforded by the shielding between the bandpass coils?
Thanks for any clarification or info...

tnx vy

From: Bob <balbert@cnmnetwork.com>
Message-ID: <eggV4.56511$701.792991@news4.giganews.com>
Source record: 60535

Joel, the coupling between the resonant circuits determines the bandwidth. Tight coupling means wide bandwidth; conversely, loose coupling will give narrow band pass.

However, the bandpass of a single tuned circuit of ordinary Q is fairly wide, so the coupling between the circuits needs to be controlled to achieve the best compromise.

This is not a simple subject, and it's worth spending some time reading about it. There are many classic texts on the subject.

This is generally done at VHF. Loose coupling generally means steeper skirts. At VHF, the few pf between nearby circuits can represent a lot of coupling (low impedance). This tends not to be needed at HF.

>On a similar note, how is a fairly broad band-pass achieved, so that the

>Thanks for any clarification or info...

In general, yes. You almost need to model these circuits as surprising things sometimes happen, but in general, more coupling means a broader passband. In general, though, it's not a problem to cover an entire band. Typically you want as high a Q as possible to whack off out of band signals. This is somewhat less true of bands like 6 meters where you have wide open spaces.

One more thing. I read in an old Popular Communications magazine, in "W1FB's workbench" an construction article for RFI filter power outlet. He mentioned that after he had installed the filter at his tv set AND at the ham shack the tv interference went down or disappeared (I can't remember which). If interested, let me know and I will look up the article.

I have some interference from a neighbor's TV receiver, but it's radiated, not conduced troughout the AC line. It's not very important because they don't like watching TV , but I think some type of High pass filter in the TV set antenna can help. My vertical GP is 6 meter far (or near) their TV antenna.

You could change the channel after all. I though you had to first erase it
but I was wrong. Thanks to all who replied. Have a good weekend.

Yeah cheers for that. I know that the grey stuff has carbon in it. I once made a 2 meter antenna with the stuff and wondered why it didn't work too well:)

The "plasticizers" and "fillers" are Al and Sn compounds (among others) - so they
are metals and absorptive of RF.

(oh man, it's been over 30 years since I took inorganic chemistry.)

Thanks. You have confirmed what another NG member told me in private messages. I advised him that I *did* go ahead with my plan to pull all fuses (one at a time) until I found an offending device or group of devices. As you and he guessed, it was a fuse marked "GAGE/IDLE" that fed the apparent noise-maker. He suggested bypassing the hot side of the fuse with a .01�F capacitor. I did and it worked very well.
Now, the noise level from that source is low enough to make the radio useful on all bands while mobile (at least on RX -- I still haven't received my license yet....)
Of course, with that noise gone, I can now hear some true "ignition" noise when the engine is running, but it is low enough that I can wait until I find a good deal on some copper flashing :)
Thanks to all in the NG who responded, publicly and privately. Your help was, and is, much appreciated.
Regards,
Aaron (sigh....two weeks and license still pending....)

I have all the parts (and some extras) to build a few FET RF
Amplifiers using the IRF 511/530 or similar series. Recent QST
article has a good design that gives gain right up into the 10 mtr
region..before the designs would peter out above 10 MHZ.
Anyways..I'm going to build one..and If im going to use it MOBILE..
Ill need to get the voltage supply up to at least 20 volts ..26 would
be better. Anyone got a good cct for a voltage doubler or some
kind of charge pump that is not too complicated. The regulation
would not have to be that great for my use..73 Earl VE3AB

4048. Wanted Vacuum Relays

I sold the 4-1000 tubes, but still have the cabinet with vaccum variable
15kv,
4-1000 filiament transformer, 3B28 tube rectifiers and 10kv @ 1 amp. with
transformers mounted. Chokes, Tank Coil and output network still intact.

Pole Peg transformer 220 AC in and 5545 AC out. I've ran this transformer
over an amp and it never gets warm. I suspect it's good for 2 amps. It
would
be expensive to ship. Oil filled caps are available too.

Looking for a trade. I need a Honda 350 Watt gas generator
or a big DC to AC inverter. Or...make an offer.

It shows - hardly a single word of that is true.

A PVC pipe (normal thin-wall semi-rigid plumbing grade) will change the performance of an antenna inside, but mostly due to its dielectric properties changing the resonant frequency.

>P.S. Yellow not a bad!

An old trick used for police motorbike radios was to paint the rig black to help dissipate the heat from inside, but to cover the top and sides in a clamshell case painted white to reflect the sunlight. An air gap all around allowed effective cooling of the rig.

G3XYM has solved this problem in a practical manner: he uses a 12V 12Ah gel battery. Relay switched in series with the onboard 12 V supply during transmit.
Details to be found on his site:
http://homepages.force9.net/picks/throb.htm

Best regards,
Ben PE1PDR.

Helical filters are ideal for this sort of problem. Toko makes several,
but probably not for your frequency range. You might be able to make
your own. You might find details in the microwave literature.

I've always believed that PVC was ok, unless it was mixed with something
that was conductive.

The standard example:black PVC tends to be lousy:it seems that the stuff
is made with carbon, hence it tends not to be transparent to RF.
But the white kind usually is ok.
The microwave oven test IS a good way to test a sample though.

As a first design, I would suggest a NE602-based direct conversion receiver for
80, 40 or 20 metres. I would cover a single band only - multiband equipment is
much, much more complicated than single or dual band gear.

As a beginner, do yourself a favour, and build something with a reasonable chance
of working first time. A simple receiver that give acceptable performance is much
better than a complicated and potentially high performance set that doesn't deliver.

Use a VFO separate from the NE602. If possible use a good tuning capacitor and
vernier dial. Following the NE602 should be a low noise op amp. Component
values should be tailored to reject audio outside 300 - 3000 Hz. You won't need
an RF amp for 80 or 40m. For the audio pwr amp, an LM386 is OK. AGC and
S-meters are useless frills that do nothing for receiver performance.

The above mentioned DC set gives very acceptable performance. It's not perfect,
but should be good enough to spur you on to something better. Don't pull it apart
when finished - make up a DSB or CW transmitter and make it a portable txcvr.

What is that something better? As others have said, the KK7B DC set is very good.
The 74HC4066 is an excellent balanced mixer. It also works on harmonics. This makes
it possible to make a multiband Rx quite easily using just a stable 3.5 MHz VFO.
For the VFO/buffer I used 74HC4004 ICs. This should be in its own box to prevent
hum.

The set consists of the following:

RF amp: 2N3866, 2N3053, BFY51 or 2N4427 (W7ZOI/W1FB?)
Mixer: 74HC4066 - ZS6BZP (Electronics World Feb 98)
LO/Buffer: 74HC4004
Audio stage: 3 transistors - as per KK7B
AF Filter and Diplexer - as per KK7B
AF amp: 4007 biased for linear mode

It's 4 transistors and 3 ICs. Dynamic range and audio reproduction is very good. It covers
40 and 20 metres. Apart from some hum (VFO shielding not perfect) overall performance
is first rate. Of course the audio image is an issue as it is still a DC set. On the performance:
cost scale, sets like this one and the KK7B R1 would be near optimum as they are not much
more complex than the simple designs, but give good results. The above mentioned set took
about 40 hours (over 10 days) to develop.

The receiver is the subject of a future article and further information on it is not yet available.

73,

Peter VK3YE

Well, I don't have the heart to paint mine white, from many years of working with cameras in the desert, white was the order of the day with an umbrella to boot for shade. Film and video cameras just hate heat. You can heat fog film and high speed video cameras (the older ones) could not maintain a white balance with extremes of temperatures. I found this really nice dinner napkin at one of the motels, it was as white a white as you ever saw and was linnen I suppose, slick and shiney, extra tip to the waitress let me carry one out stuffed in my pants. Shame, shame, BUT, it has done a wonderfull job of reducing the temperature of my mobile radios since 1984! Starting with an Icom 730, TS-440 and now a TS-450 and a dash full of motorolas, Just cover the rig up and lock the car up

Source record: 60465
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

A high voltage probe is nothing more than a large value resistor that will withstand the high voltage. It is used to make a voltage divider based on the input resistance of the meter. If you use a 20 Mohm input meter, then the probe will work but read approximately twice what the value of voltage is. For a typical 100:1 divider, the meter input resistance is 10 Meg, the probe resistance is 990 Meg. This adds up to 1000 Meg to 10 Meg, or 100 to 1. The same probe in a 20 Meg meter ends up with 1010 Meg to 20 Meg or approximately 50 to 1.

The common input for multimeters is 20K ohms per volt. The only meters with higher input resistance are those that have internal amplifying electronics. If it's an analog meter, then it's probably 20 K. Look on the meter face, it is sometimes stated there.

Prior to my ordering the 100kHz crystal from Digi-Key, I tried various unmarked crystals from surplus computer motherboards, etc. in the circuit by soldering them into an old FT-243 holder and plugging them into the Swan's crystal socket. I suspected most of them would be low-frequency watch crystals (32 kHz or something?) for the on-board clock, but I hoped I'd get lucky. They were identical in physical dimensions to the 100kHz rock I got from Digi-Key, but I never heard ANYTHING out of them at all. Now whether they just weren't oscillating, or they got damaged from too much drive, I can't say. I think I'll try the IC inverter chip oscillator you mentioned in your other post to see if the ones I tried in the Swan are still functional now. I can judge my chances with the new rock from Digi-Key after that.

> calibrator circuit.

> 2) Get an AT cut based calibrator running with a crystal at
> something like 6.4 MHz and a divide by 64 chip to do the same thing
> with much better accuracy and stability.

Later models of the Swan (the 500CX) had a 100/25 kHz transistorized calibrator in place of the tube calibrator in the model I have here. That seemed much more fuctional, so I was contemplating making an upgrade anyway. Especially since our regional Net and calling frequency is on 3750, and a 25kHz calibrator would enable him to tune it dead on

instead of swishing the dial around waiting for someone to talk. If I'm going to build something, I might as well go up in frequency and use a /N chip as you and WC1F suggested, anyway. I was looking to plug the new crystal into the old circuit just for convenience (not having to hack everything up) and speed (getting the rig back to the owner).

The Swan 500CX calibrator design didn't impress me much. I don't know what style of crystal they used in that version, I've never seen one: http://www.voyageur.ca/~lowsar/temp/500cxcal.gif

Here's the one I'm working with: http://www.voyageur.ca/~lowsar/temp/500cal.gif

This is not my field of expertise, but I do know that when I was working on the design of microwave hybrids, and we used IR scanning to determine temperatures, we used charts of material emissivity to correct the observed temperatures. An alumina substrate and a gold transistor package can be at the same temperature and measure differently on the scanner.

Yep. That's why when we try to cool "low grade" heat sources such as the pass transistor in a power supply, we use black heatsinks.

>IR on top of it.

Good stuff.

Actually there is a "selective material" involved here and that is the window glass in the vehicle. This probably is different within the same vehicle as the windshield is constructed (and tinted) differently from the side glass. Then there is the dependence on whether the solar radiation is direct or diffuse (cloudy day), the angle of incidence on the glass, (how much is reflected) et cetera...So as you say, this is an academic exercise but we don't have all of the necessary data.

>> Thanks,
>> any help will be really appreciated

I feel I should comment here to inject a word of safety. While
technically correct that a high voltage probe is nothing more than a
large value resistor, there are some other design considerations
which must be considered. Firstly, the insulation on the probe must
be able to withstand the voltages being measured. It's no fun to
have a flashover occur while you're holding the probe on a 30KV
circuit. Don't forget, too, that probes may get dirty or wet, and
that this can significantly reduce their voltage handling capacity.

Nextly, the high value resistor must be able to take the voltage
applied to it. Not all resistors can withstand high voltages, and
they may flashover or breakdown. If this occurs, the minimum damage
you can expect is to fry the meter (Worst case might be frying
yourself!). The power handling capability of the resistor probably
won't be a problem, but it would be good engineering practice to

work the equations to make sure of this.

Another concern involves the switching of the meter. If you're using an older style meter with a mechanical switch, what happens when you operate the switch? Is the input disconnected from one contact before making with another contact? What will be the voltage on the switch when the contacts break? Will this cause the switch to arc over?

Finally, if you're going to be measuring AC voltages with the probe, you'll have to consider the aspect of any capacitance associated with the meter, leads, or probes. 1000M of resistance can result in a significant RC circuit.

So, before attempting to construct your own high voltage probe, please spend a few minutes considering the failure modes possible and the consequences.

Dave

P.S. Standard Disclaimer: I work for them, but I don't speak for them.

I have heard many FT 1000MP owners with nice well-rounded transmit audio. In many cases they have extremely good bass response. I have heard that this kind of audio can be achieved by adjusting settings in the hidden menus as well as the normal menus. Are there any 1000MP owners out there that can offer suggestions as to the best settings in order to get this nice full audio sound. I find audio like that is very comfortable to listen to when conditions are good. Of course I would reconfigure for a narrower sound when working DX. Thanks in advance for any advice.

Also Wilson Valves in Huddersfield.

AR88 is a complicated beast, well not that complicated as it is a
straight superhet, but there is a lot in it.

Right, what could you find.

Firstly, DO NOT run the set without either phones, loudspeaker or a 3
ohm resistor across the LS terminals. The output transformers have a
habit of popping and you wont be able to find one.

Secondly. Check all of the wiring underneath. There should be a huge
wiring loom and any bits that have been mucked about will standout like
a sore thumb.

Thirdly, if you want to redo the IFs then a wobbulator is best so borrow
one before wandering straight in. The RF section is ok with a sig
generator but the IFs need setting up properly.

They do suffer from old paper capacitors. There was an article in the
shortwave magazine of some time ago where a complete rebuild was
described. This will be distinctly non original but it will work well,
depends what you want.

Mains smoother also goes. Noticeable if there is a lot of sticky oil
around the rear of the chassis. Its an oil filled paper capacitor,
again one you will be unlikely to replace.

Get a manual. Tudor Gwilliam Rees (Savoy Publications) will flog you
one. The manual contains the alignment instructions as well as the

circuit diagram.

Finally, which one do you have?. Many of them have had S meters fitted in the front panel which involves removing the name plate. It will probably be a D or an LF. If you can't see a name plate the try the following:

1) Look at wave change switch. If bands continuous from 0.54 MHz to 32 MHz then D. If a longwave band then continuous from about 2MHz up its an LF.

2) Look at back. If a neon fitted near the antenna terminal then its an LF.

Finally - good luck. They are nice sets and well worth restoring if you have a good one. You will develop arm muscles like mike tyson and possibly a hernia. buts that's all part of the fun.

Where are you? I have one of these beasts and have done several repair and tweak jobs to it.

Regards

Robin

Alan,

Both circuits you show are from pretty far back. I would not try to go much further with either one of them.

JAN crystals used to have (15 years ago ....) surplus 6.4 MHz crystals pretty cheap. They made a nice calibrator. A pair of divide by 16 IC's got you down further than you ever needed to go. I suspect they sold out of the original batch by now ..... Hopefully there are more out there.

4071. FS: Unbuilt Norcal NC-20 QRP CW Transceiver Kit

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-22 00:00:00 UTC
From: Michael Melland <badger@vbe.com>
Message-ID: <3929C3DC.C6563C19@vbe.com>
Source record: 60476
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.swap

Selling an unbuilt NC-20 kit with optional 10-turn pot. This is the great 20 meter kit that Norcal sold limited numbers of about a year or so ago. I opened the mailing box but haven't ever got around to building it..... and other projects now are calling, so it's for sale. Transceiver kit consists of board, all parts, heavy aluminum pre drilled enclosure, and all controls and knobs. Kit has AFA annunciation to give you your freq in cw as well as a built in TICK keyer.......... output about 5 watts +/- and it is adjustable.

For specs and info see:
http://www.fix.net/~jparker/norcal/nc20/nc20update.htm

Selling price is $110 USD shipped in USA (Canada a little more) We members of Norcal agree not to make money on these projects so I'm selling it at just what I paid for it with the extra 10 turn pot.

Send me an e-mail if you are interested.

I have 12 homebrew radios for sell. All use one tube, and are of the
Twinplex Regenerative Type. All are fully tested.

Six are "Tom Thumb" models. Just 8 ounces, and measure 3 x 4 x 4.25 ". Their
frequency coverage is:
3.3 to 6.2 mhz, with fine tune, 6SN7 tube
9 to 16 mhz, with fine tune, 6BZ7 tube
3.6 to 4.1 mhz, 80 meter model, no fine tune necessary, 5BK7 tube
11.4 to 17.5 mhz, with fine tune, 6SL7 tube
5.6 to 11.5 mhz, with fine tune, 6BS8 tube
9 to 16.5 mhz, no fine tune, 6SN7 tube

Group photos of the Tom Thumbs are at::
http://nellie.bcinet.net/darla/tom1.jpg
http://nellie.bcinet.net/darla/tom2.jpg
http://nellie.bcinet.net/darla/tom3.jpg

The other six are larger models, measuring 4 x 4.5 x 5 inches. They use
larger antique dials. Frequency coverage is:
9 to 19 mhz, with fine tune, 6SN7 tube
.550 to 1.555 mhz broadcast model, no fine tune necessary, 6BK7 tube
3.2 to 9.8 mhz, fine tune, 6BS8 tube
7.6 to 17.5 mhz, fine tune, 6SL7 tube
5.8 to 16.5 mhz, fine tune, 6SL7 tube
3.4 to 8 mhz, fine tune, 6BQ7 tube

photos of these models are at:
http://nellie.bcinet.net/darla/tom4.jpg
http://nellie.bcinet.net/darla/tom5.jpg
http://nellie.bcinet.net/darla/tom6.jpg
http://nellie.bcinet.net/darla/tom7.jpg

All require 6 vdc filament voltage, and 32 to 54 vdc plate voltage (9 volt
batteries in series). All receive SSB signals as well as AM. Price of any
model is $50 shipped in the US. This reflects the cost of the parts, and a
modest charge for the labor of assembly.

Reg-
Your suggestion is a good one. The elementary part would have to include more than a paragraph of explanation of why/how.

Bias is what I am concerned with mostly. The reason to bias is simple, it needs some current in the base to turn it on. I want to know how to determine how much and the effect on the other end. Also what current is essential and what current is not. I have a very basic circuit, collector feedback bias, common emitter, with a 330 resistor in parallel with the collector/base junction and a 1K resistor above that. The !K resistor is in series from the battery to the juntion of the collector and bse bias resistor.

There is no emitter resistor.

the kind of things I want to determine are the idle current, base current, emitter current, DC inout resistance, DC Output resistance, AC input impedance, AC output impedance, methods of coupling stages, how much feedback is enough to oscillate a stage, how much input impedance is good for buffer amplifiers and such.
I want to be able to determine the biasing and coupling using Voltage Divider, self bias etc.

Tall order?

Dan OM,

The 'Screwdriver' mobile antenna enables remote tuning over several bands, from the driver's seat. It always requires a top whip to function, as do all vertical whip mobile antennas. You can make your own or purchase one from several vendors. It is an expensive, bulky solution as mobile antennas go. What price multiband remote-tuned operation? That depends on your operating style.
As for me, I have been running mobile CW for almost 30 years now, and I have found no need for band changing on the fly at all. So I use single-band Hustler resonators, whip, and bumper mount on my three cars. Works like a champ, and is cost-effective. I remove my whip every day at work and store it inside, because I cover my car (keep sun off it). Only takes seconds to remove or reinstall the entire antenna. No coil springs or guy lines are required. This is a big advantage for my kind of usage.
All center-loaded antennas of reasonable construction exhibit similar radiating efficiency, Screwdrivers included.
I highly recommend that one do some mobile operation FIRST, with single-band antennas, and then determine their need for multiband operation, if any.

73,
Don, W6JL

>Leon
>--
>Leon Heller, G1HSM

well, I would say - coax cable filters are ideal to sort of the
problem, but you need to use heliax cable, and the circuit is somewhat
more elaborate than just pure coax cable, it is a smaller coupling
capacitor and a tuning capacitor down near the end

once made such filter to improve 2m repeater filter, with only 600kHz
between pass and notch frequency, it is a relation between the notch
depth and frequency separation, so for this repeater application the
filter has only 15dB noch, but it is worth it - compared to other
filters for similar improvement

DL7ZX also describes an application of xtal filters, they are
sometimes very useful, he used such filter to remove blocking of a 2m
beacon mounted on same site as repeater, with 300kHz frequency
difference

What kind of filters and what kind of design? I believe you can get
SciLab (for free) for Linux, and it has some good tools for making
digital (discrete-time) filters and for finding pole and zero
locations for continuous-time filters. I use it regularly for
both...but that might not be at all what you're looking for.

Cheers,
Tom

Source record: 60408
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur,sci.electronics.basics

Hi Group:

I have a number of schematic diagrams with crystals in one frequency
or Variable with loading. How does on create an equivalent circuit with
the same characteristics of a crystal? what is involved?
1. I would assume a resistance of the crystal itself
2. I would assume an equivalent "loading" to match the capacitance of
the crystal
3. Maybe Q is important?

I would, given my understanding, that the crystal has a high internal
resistance? One cannot just replace the crystal with a tuned series or
parallel LC combination.
Am I rehashing an old subject?

I bought several microwave mixers at Dayton. They are a little aluminum block with a WR34 waveguide output, a SMA LO input and, a SMA IF output. They were made by Marki Microwave and they were designed for harmonic mixing. At $20 a piece they were a good deal and the vendor must have been over a hundred of these parts.

Unfortunately, I did not get the name of the vendor. If you know who the vendor is and how I can contact him, please email me.

Thanks,

Hello,
I don't know if your design is flexible or not, But if you want a really inexpensive way to program a micro controller in BASIC, try BASCOM-AVR for the Atmel AVR micro controllers. A free demo is available that will program up to 2k, the limit of on chip flash in some of the processors. Which is another plus, Flash is reprogrammable, no OTP devices. The programmer is a simple connection to the parallel port on a PC, BASCOM-AVR programs the chip for you.
I am in no way associated with either company, I just downloaded the software, and ordered some parts online. AVR micro controllers are available from a few companies for online order.

http://www.mcselec.com/

Also Dontronics has a board and kit available for the AVR,

First of all, those old calibrators usually used a 100 kHz crystal. Since they were in an oscillator circuit that was class C (or close to it), the waveform was usually a sinusoid clipped on one peak. So it was rich in all harmonics.

It's very rare to have a good square wave in such circuits. So there is never a problem getting strong signals on both even and odd harmonics.

OK, you guys, any ideas as to what the numerous Shortwave "Numbers" stations are? Is there a hidden code in the numbers themselves? Perhaps there is some kind of tone encoding. Maybe there is interaction between Numbers stations on seperate frequencies, and where abouts are they transmitting from? I thought the cold war was over..... Maybe there is a simple explanation to all this...

cu-r on (default)
An-r on(default)

8-2 Split operation nor(default)

8-4 Front end RF amp Flat for all band
operation/ Tuned for
ham bands only.
I use tuned mostly.

8-9 r-LSB carrier -0.000
t-LSB -0.100
Proc-LSB -0.050
r-USB carrier -0.000
t-USB -0.100
Proc-USB -0.050
t-A3-car -1.080

Here is how to get to the "hidden menue". When
you bring it up, record EVERY setting in case you
mistakenly change something.

With radio in OFF position. Push "FAST and LOCK", then POWER ON.
Release buttons. Select
normal menue by pushing FAST and ENTER. Dial
up past 8-9 and there is menue 9.

To make radio xcve everywhere go to 9-9 and
select GEN.

To vary IF rx Gain, go to 9-1. I raised mine from 10
to 12.

Hope this get's you started and have fun.

POWER on SETTINGS

28 + POWER Resets ALL menu settings to factory default.

SUB + ENT + POWER Resets ALL memories (except menu settings)
to factory defaults.

SUB + 29 + POWER CPU Master reset for ALL memories and menu settings.

4101. I nned a book on Transistor Circuit Design

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-23 00:00:00 UTC
From: Curtis Scholl <cscholl@izzy.net>
Message-ID: <P9uW4.141$xJ2.1778@news.itd.umich.edu>
Source record: 60487
Cross-posted to: rec.radio.amateur,rec.radio.amateur.homebrew

To Whom it may concern:

I seek a book on electronics/transistors with a concentration on biasing transistors (bipolar/mosfet/jfet etc) that doesn't leave one hanging.

I had a book by Malvino, Yellow binding, printed around 1973 as a textbook in college. I think it was "Electroncis Principles".

In the book there were explanations and experiments based on instrumentation. There were diagrams of configurations, hybrid parameters, both DC and AC.
It was a wonderful book but it assumed too much would be remembered from one experiment to the next. It left me behind 25 years ago.

I want a book that is for designing transistor amplifier, oscillator, and buffer stages for common emitter, common collector, common base and the bias methods like self bias, voltage divider bias, collector feedback bias, determining the load line (without a transistor tester) based on the parameters of the device.
I don't want the answers, just the means to determine the answers from the hybrid parameters and their relationships.
I would like to be able to calculate the input impedance
and the output impedance of an AC circuit.

I would prefer a book where transistors are not subset of a larger book. The book I seek is only about transistor circuit design. I would prefer a practical versus theoretical design base of knowledge. Voltages using Electron Flow would be desireable. The book should have more of an explanation of the parameters involved than my old Malvino book did.

I have the design manuals of W1FB and the ARRL. Even "Solid State Design for the Radio Amateur" leaves something to be desired. It is a great book, but unclear in some areas that I would prefer to be knowledgeable in.

Any one out there have any suggestions?

I have been to Borders, Barnes & Noble, and no soap except large books with calculations and no real explanation.

Thanks in advance

Curtis Scholl

I can think of two, no three, ones that might help. One is in the ARRL library, it is an RF design book, soft covered in red paper. Can't remember the exact title. The second is Handbook of Electornic Calculations - McGraw Hill, hard bound, it covers a lot more than just amplifier design so you may want to borrow it rather than buy. The third is called, I think, transistor circuits. All of these treat bipolars fairly well, they are not so good with FETs.

I must admit I find this book a bit on the theoretical side. It's
great if you know the basics of solid-state design (and/or have a
degree in mathematics) but as an introduction to practical
design it leaves a lot to be desired.

Perhaps a couple of the chapters from "The Art of Electronics"
(Horowitz & Hill) are better suited (although they treat mainly LF circuits).

I would really like to see other suggestions...

May I suggest a book of elementary transistor theory which will
includes the principles of transistor biassing. Nearly all components
in a transistor amplifier are there just for bias and decoupling. Its
a relatively simple subject. You would then be able to draw your own
circuits with component values. Much more satisfying.

I can't give you any specifics.

But there have been articles about biasing bipolar transistors in various hobby magazines over the years. They'd include equations for getting the right values, but they were a generalized approach.

Once hand held calculators became cheap, I think we saw a rise in equations in the various ham magazines. In the late seventies, Ham Radio magazine had a number of articles about using programmable calculators to design various things that most up till that point would otherwise have picked out of a cookbook.

One series in QST comes to mind. It must have been 1974 or so. "Learning to Work with Semiconductors". It went through quite a bit of territory, with practical circuits but also equations. I can't remember if it dealt with transistor biasing, but I do recall that it was a good place to look for how to compute capacitor values in various oscillator circuits, and figuring out transistor power output circuitry. It was not for the professional, but for the beginner who wanted to do more than copy a circuit from somewhere.

For a while, the ARRL published a booklet that contained the articles in that series, but it didn't seem to be available for all that long. I thought that was a mistake. While some of the material ended up in other ARRL publications (I see an echo of it in Solid State Design for the Radio Amateur), it is a shame they didn't keep it as a book. Of course, with QST on CD-ROM, the series is readily available now.

Someone mentioned "Introduction to Radio Frequency Design" by Wes Hayward and now published by the ARRL. I think it's a worthwhile book but it's a bit hard to place. It covers some areas that isn't covered in the usual ham books, or in a different tone, but in some areas I was expecting deeper coverage. My reason for mentioning it, though, is that it comes with a disk of programs for computing various RF-related items. I can't run it at the moment, but I recall there is a program for determining the biasing of bipolar transistors, and another for biasing FETs., along with programs for designing filters of various

kinds.

I am also looking for a simple DTMF decoder project.

I need to connect the external speaker output from a Amateur Radio to a DTMF decoder board that will allow me to switch 12 relays on and off by transmitting standard DTMF tones to the receiver.

The idea is to make a small controller for a 10GHz ATV transmitter. For example, A DTMF tone of "1" will turn the TX on. A DTMF tone of "0" will turn the ATV TX off. A camera will be mounted on a swivel mount and a DTMF tone of "2" will raise the camera and a DTMF tone of "8" will lower the camera. A tone of "4" and "6" will move the camera left and right.

A few years ago I had a project made from a IC called a M967 that allowed DTMF decode in this way. I am looking for a similar design to make. I have since lost the design and am looking for a similar project.

I look forward to your reply.

The Bergen Amateur Radio Assn (BARA) is holding is
Spring Hamfest Saturday June 3rd, at the
Fairleigh Dickenson University parking lot, located
just 10 minutes from the George Washington Bridge
in Teaneck, NJ.

See information on the BARA website at
www.bara.org

Buyers, arrive at 8am, $5 entry fee.
Harmonics free, as well as XYL's.

Sellers begin to arrive at 6am., $10 per space.
Limited AC Power spaces priced at $20.

VE sessions
Ham flea market
refreshments available.

One of the largest hamfests in the tri-state area.

Hope to see you there...

As was pointed out the very old ones used the 100 khz crystal and did not use a devider. The newer ones did and then some were operated around 1 mhz and used a series of flip-flops to generate markers every 25 khz or so. Probably when the square wave hit the first tuned circuit (even stray inductance and capacitor) it rounded off the square wave and generated the even harmonics.

Source record: 60419
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur,sci.electronics.basics

Curtis,

Assuming it is an AT cut crystal and running at typical HF band
frequencies the crystal probably has:

Q > 50,000 , might be > 500,000
Resistance < 60 ohms, might be < 10 ohms
Temperature stability 0 to 50C < +/- 100 Hz at 10 MHz, might be < +/-
20 Hz
Time stability < < 0.1 Hz per day at 10 MHz

The crystal is commonly modeled as a series tuned circuit with an
additional capacitor across the whole thing. For a bunch of odd
reasons this can look like a parallel tuned circuit at some
frequencies.

Your best bet is to build a VFO with the range you are looking for and
feed it's output into the crystal socket on the radio. That way you
can optimize the VFO and you don't mess up the radio. About all it
will cost you is another transistor and about 3 ma or so of current.

Hope this helps

Curtis,

In a nutshell -

BIASING CLASS-A JUNCTION TRANSISTORS

Class-A means the collector current is never cut off during the signal input voltage swings such as in a microphone amplifier. All the rest is a simple application of Ohm's Law.

There are two characteristics of the transistor of importance -

Vbe is the emitter-base voltage needed to turn on the transistor collector current. For silicon transistors it is 0.65 volts. For germainium transistors it is 0.15 volts.

Beta is the current gain Ic / Ib, the DC collector current divided by the DC base current. The value of Beta is obtained from the data sheet. For small-signal types at audio frequencies it is usually between 50 and 300. The exact value doesn't matter. If you don't know have a guess at 100. This allows some calculation so be done in the head.

Obviously, DC emitter current = collector current plus base current. But current gain is so high, for many purposes the collector and emitter currents can be considered to be equal.

For small signal amplifiers think in terms of milliamps, k-ohms and volts. Base currents are in microamps.

The most general circuit is a transistor plus 5 resistors. Get yourself familiar with the standard values in the +/- 5% tolerance range. Resistor values increase in 10% steps. There's also a DC supply Vdc.

Draw the circuit :-

R1, R2 and R3 are all in series across the supply Vdc with R1 connected to Vdc.

The junction of R2 and R3 is connected to the transistor base.

R4 is the collector load resistor between the junction of R1 and R2 and the collector. It need not be a resistor. It could be the primary winding of a transformer, or a tuned circuit with negligible DC resistance.

R5 is the resistor between emitter and the grounded side of Vdc.

For good stability versus temperature and time there are two things to remember -

(1) There must be DC negative feedback from the collector or emitter circuit to the base. R1 and R5 provide this feedback. If this most general circuit is simplified either R1 or R5 may be removed. But NEVER remove both. Negative feedback also ensures that differences in Beta between one transistor and another have little effect on circuit operation.

(2) The bleed current through R2 and R3 must be considerably greater than the base current. As a rule of thumb it should be 5 or ten times greater. I like 10. This ensures that changes in base current due to changes in Vbe due to temperature, do not signicantly change the voltage across R3. If the volts across R3 are stable then all other circuit voltages and currents will be stable.

Begin by choosing values for the collector current and bleed current through R2 and R3. Don't choose a much greater collector current than necessary to supply the signal current to the next stage. Especially if the equipment is battery operated. The base and emitter currents can then be calculated.

The total current from the supply is the collector current plus the bleed current through R2. This is also equal to the emitter current plus the current through R3. It may seem obvious but it is always advisable to check.

Then allocate voltages to the junction of R1 and R2, and to the emitter. The peak signal voltage expected at the collector must be taken into account. The collector signal voltage must not be allowed to swing within about 0.5 volts of the base voltage or signal distortion will occur.

The emitter to ground voltage should be 2 or 3 times greater than Vbe. This swamps changes in Vbe due to temperature or to variation between one transistor and another..

The voltage across R3 is then emitter volts plus Vbe.

The currents in all resistors and the voltages at all circuit nodes have now been estimated and the resistor values can be calculated. Select the nearest resistor values from the 5% tolerance range. Check that R2 and R3 are not so low in value as to divert the incoming signal current away from the transistor base.

The base signal input resistance is 25 * Beta / Ie ohms where Ic is emitter current in milliamps.

Being obliged to select from preferred resistor values will slightly upset the originally selected DC circuit voltages and currents. So now recalculate everything starting this time with known resistor values. It might be necessary to make judicious changes in one or two resistor values or voltages. But it's a very uncritical matter. The DC

feedback makes for an easy life.

The most sensitive part of the circuit is the ratio of R2 to R3 which determines the voltage across R5 and hence also the collector current. (The circuit at DC is an emitter follower).

If R1 is not zero then the junction of R1 and R2 is normally decoupled to ground via a large value capacitor.

R4 can be set to zero and R1 can become the collector load.

R5 can be decoupled to ground or part of it can be left un-decoupled to provide negative at signal frequency. This also greatly increases base input impedance of the ampkifier. Zin = Beta*R5.

The output signal can be taken from the emitter. The circuit is then known as an emitter-follower. High input Z and low output Z.

The most simple circuit has all resistors removed except R1 and R2. This is suitable when the collector DC voltage is not of great importance such as very small signal amplifiers.

Incidentally, the voltage gain for silicon at LF in the above circuit is always 40 times the DC volts-drop across the collector load resistance. Not everybody knows that.

With a little practice and a pocket calculator you will be able to design circuits in a couple of minutes. Its great fun especially when a circuit is put together and the measured DC voltages are all in their predicted ball parks.

4117. Any QRP'rs in the Mobile Alabama Area

Newsgroup: rec.radio.amateur.homebrew

Anyone in the Mobile Alabama area that wants to do some local QRP'ing?? I've got at Pixie II that I want to try out with some Near Vertical Incidence Signal (NVIS) propagation. The signal is much too underpowered for night time operation with the QRN so terrible. We could try during the day when the QRM is down.

Thanks!
Bill

Hi :

I am in one of those "touchy feely" areas of the country where technical thinking is not considered good form. The popularity of books of a technical nature are less important than those of the "politically correct" variety. Rocketry is not even represented except as a model rocket venue. Amateur Radio is represented only by the ARRL Handbook. While the ARRL books are good, they don't through my thick skull.

See ya!

The Nat Semi "Power Devices" handbook has a number of boost designs - or search their website for "boost regulator". There are older and available devices which can be pressed into service - like the LM3524 or LM3525 as pulse width modulators - for this application.

Many years ago (1975?) I owned a TenTec Triton IV (aka Model 540).
Then I was lucky enough to stumble onto and buy an external VFO for it.

Using BOTH the internal and external VFO's at the same time gave beautiful
"dual-frequency" reception--I loved it! (Later it was "creamed" beyond
repair in a car accident!)

Maybe you could purchase a manual (mine came with schematics) for the
540/Triton IV and the external VFO by calling TenTec?

SciLab is definitely not what I was expecting, but it looks interesting
enough that I'm going to get it and install it. It may well do the job.

I'm mainly interested in keeping something around for those quickies.
Right now I'm playing around with some all-pass (phase-delay) ideas,
but from time to time I cobble together all sorts of short-term solutions
to test situations and crazy ideas that increase my understanding of
what the books have told me.

4125. Re: how to Replace a crystal in a QRP rig with a tuned circuit

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-24 00:00:00 UTC
From: Roger Leone <arleone@inreach.com>
Message-ID: <A_UW4.16$q5.247@news.inreach.com>
Source record: 60430

Curtis:

Some crystal oscillators can be converted to variable frequency oscillators (VFO) simply by substituting a parallel resonant circuit made up of a coil and capacitor. However, that is not true for all crystal oscillators, so you can't assume it will work for yours. If you want to convert a crystal osc to a VFO, you should first determine what type of oscillator you have to begin with, such a Colpitts, Hartley, Pierce, etc...then look for a schematic of a VFO of the same type. That way you won't be changing things too drastically and you will have the highest chance of success.

By the way, many crystal oscillators can be varied over several kHz by putting a variable capacitor in series with the crystal....these are VXO's (variable crystal oscillators). Over a resonable tuning range, they maintain the stability of the crystal.

Stability is something not easily attained with VFO's, especially if you are converting a crystal osc that was designed with the thought that the crystal would keep the osc on freq. When you convert it to a VFO, the stability of the crystal is lost and you will end up having to find the right combination of temperature compensating capacitors to keep it from drifting around.

Instability is a nuisance on receive and can be illegal on transmit.

: of mine queried me about this, and I didn't have the foggiest notion
: how to answer:
:
: If the square wave is made up of the fundamental and a series of
: diminidshing *** ODD *** harmonics, how come the calibrator works on
: ALL harmonics?

I recently investigated this issue for a receiving converter. Thanks to
help from Ravi Goonasekeram (KA3NNJ), I learned that any mismatch between
the oscillator and its load, that is, any complex impedence that the
square wave travels through, distorts the oscillator signal sufficiently
to include even harmonics. You can think of it as an effect of
smothing the sharp edges of the "perfect" square wave.

Not everyone has a decent library in reasonable reach. Even the few good libraries in my area have little in the 621 section, and most of that is really really old, and I already know how to tap my 6AQ5 to see if it's microphonic, thankyewverymuch.

Now, my library can get *some* of the books that I request through the interlibrary loan system. But first I'd need a title. So I'd come to a Usenet discussion group and ask for suggestions. You know, just like the original poster did.

Consider yourself fortunate that the libraries in your area don't spend their entire budgets on romance paperbacks, video tapes and rap CDs.

not sure what you mean by 'slow morse' as 100LPM (20WPM) requires 17Hz
bandwidth to pass.

My receiver is LwEa which may be compared to BC453, used 800Hz IF
bandwidth and DSP-9 set for 100/200Hz, the worst problem was tuning
accuracy - the 60 year old boatanchor isn't made for such demands, the
lack of selectivity is compensated using DSP-9 in the audio
(loadspeaker) circuit - I do not call it receiver selectivity, would
say that 500Hz IF bandwidth is more normal for a receiver

Source record: 60439

Well, if I was specifically trying to generate all harmonics, I'd generate an impulse once per cycle. You can come close to that with some simple circuits such as a NAND gate with one input fed directly from the 100kHz square wave, and the other from a slightly-delayed version: just an RC delay, or in fact, just an R in series, relying on the gate input capacitance and stray capacitance to generate the delay. For example, if you generate a 5 nanosecond wide pulse once every 10000 nanoseconds (100kHz repition rate), you'll spectral lines every 100kHz, and their amplitude will be "flat" within about 0.3dB out to 30MHz (if I did the math right!), and about a 5 millivolt amplitude each assuming 5 volt CMOS logic. Narrower pulses extend the useable bandwidth and lower the amplitude per frequency. You should be able to get very useable harmonics out through 440MHz with AC logic and narrow pulses. (You don't have to use narrow pulses, but the spectral "envelope" of harmonics is a sin(x)/x shape, which has nulls, and you'd want to avoid making the pulse width such that you had a null on the band of interest!)

There may still be some Agilent/HP ap notes on step recovery diodes on the Agilent web site. Those diodes are specifically used to generate impulses for generating microwave harmonics.

Cheers,
Tom

4136. TS-930S help please

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-24 00:00:00 UTC
From: Anthony Roskilly <Morse.Key@btinternet.com>
Message-ID: <8ghlqj$7gj$1@neptunium.btinternet.com>
Source record: 60441

Hi, I have a "dead" TS930SAT and have been advised that the fault is likely to lie with some zener diodes and
their assoicated 2 watt resistors: R7 R8 R9 R10 D6 D7 D8. My problem? (how long have you got) but the problem
with the rig ! I can't locate the components in the rig!

The schematic shows the components near to the Digital Unit, but I've removed that and at the board beneath that
and at the main board underneath the rig, and at the power supply board beside the mains transformer, but I've
still not found the ******* things, the 2watt resistors should be very obvious.... can anyone out there help pls?

I really want to get this rig back on the air as it has all filters and the atu and works brilliantly on CW, I was hoping
to have it ready for WPX this weekend but I don't think thats going to happen.

>all this...

This is more of a question for rec.radio.shortwave, but the various articles in some of the SWL magazines (like Monitoring Times, www.grove.com or www.grove.net or something like that used to be their URL) concluded that they are the communications from the various intelligence agencies to their covert agents in the field. By keeping it simple, all the agent needs is a common shortwave radio and the one time pads giving the decryption keys. Having hidden codes would require more complex hardware which could be found and used as evidence. To prevent traffic analysis from revealing anything, the channels are kept busy with dummy traffic, so that changes in actual traffic indicating some new activity are masked.

By the way, if you didn't know, the mathematical model for a square wave is a Fourier series of this form (I forget the constant):

i(t) = I?/pi [sin t + 1/3 sin 3t + 1/5 sin 5t + ...]

In words, a square wave is composed of an infinite series (sum) of sinusoidal components equal to the fundamental plus one-third of the third harmonic plus one-fifth of the fifth harmonic, and so on.

I'm pretty sure Fourier is right, so I know something else must be going on in the calibrator... anybody know?

I have not worked on a TS930 for a long time. It appears that you have a unit with the serial number above 310XXXX. If you look for a three pin connector on the digital board labeled number 1 and follow that cable you should find these diodes mounted some where on the frame of the radio. I am not sure where the resistors are but I believe that your problem should be on the power supply board that has the large filter caps. The cable that I referenced goes to the signal board to connector number 29. Hope this little help is enough for you.

Hi,

My appologies up front.
This is WAY off topic but I need input from some practical folks.

I am making several different op-amp circuits for my homebrew gear.
Some circuits use a mic preamp LF356 driving a NE5532 headphone amp,
dual 9v batteries, and drives two 32 ohm earphone elements (16 ohms).
Problem is the circuits oscillate/motorboat or mute at low frequency.
Bypassing the elecret mic seems very critical to avoid motorboating.

I sure can use your recommendations for text/software that helps
me understand how to estimate stabilty of the whole opamp circuit.
LIKE to use WINSPICE 3 if possible. Any newsgroups I should monitor?

Need pointer to "cookbook" and "software" such as
Schauman's Outline that includes practical examples of
how estimate stability and fix, including "BODE PLOTS"?

Thank you for any help and 73, W6MIK

Look back in the ARRL Radio Amateur's Handbook volumes from the
1960s through the early 1980s. I've seen several under-500 Watt
amp project in various Handbooks over the years. The hard part
about building an amp these days is the power transformer. New
ones cost a fortune. Have you considered buying a used amp such
as a Heath SB-200? They go for about $300.

4146. what might happen....microwave tube...

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-25 00:00:00 UTC
From: mcalhoun@ksu.edu
Message-ID: <8gjssb$sqe@unix1.cc.ksu.edu>
Source record: 60302

I've recently been the fortunate recipient of several discarded (but NOT necessarily defunct) microwave ovens, dismantling them for parts, especially two "neat" really-strong magnets per tube! I "stack" them on a wooden dowel/post and watch them "float" in the air:

```
+-+<-- dowel (about a foot high)
| |
===========
| |
| |
===========
| |
===========
| |
=========== Bottom magnet
WOODEN BASE
```

but my question concerns what might happen if I tried running one of the tubes (before removing the magnets, of course). All three ovens had schematics inside, so I'd have no problem re-connecting the appropriate wires. But I wonder just how the microwaves exit the tube? Do they pretty-much go in the direction the hole in the end of the tube (which is concentric with the holes through the magnegs) "points", or do they "spray" out in (almost) all directions like light emits from an ordinary incandescent lamp?

Lest anyone be concerned, I'm not particularly worried about the safty aspects--I (think I) have enounh brains to be elsewhere than the near vicinity of the tube if/when I try it, but none of the "fields and waves" courses I took (oh, so long ago) in college actually included any practical aspects of generating microwaves in them, and I'd like to try.

Maybe I can make an anti-roach gun to operate in my garage overnight, or, if the waves will be pointable, maybe I can make an anti-mouse gun and leave it pointed at a mousehole in my barn. (I've caught seven mice in an outbuilding in the last three nights, so I should have plenty of "experimental subjects"!)

I'll probably trot one of the tubs up to the local university and see if any of the professors up there have any idea, but I'm also open to suggestions from y'all.

Although my copy is dated 1971, I recommend John D. Lenk's "Handbook of
Simplified Solid-State Circuit Design", which provides rule-of-thunb
approximations for selecting solid-state and IC circuit values .... and
features a simple, practical treatment of circuit design.

Newer and more comprehensive (and MUCH more expensive) than Lenk's book
is Horowitz and Hill's "The Art of Electronics"!

4149. Re: Calibrator Harmonics

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-25 00:00:00 UTC
From: Tom Bruhns <tom_bruhns@agilent.com>
Message-ID: <392D868E.7E1BAA6D@agilent.com>
Source record: 60305

Hmmmm....I think this explanation is a little misleading. Simply
putting a complex load on a linear square wave generator won't
generate any harmonics that aren't already there. I believe you MUST
have a nonlinearity somewhere to generate the harmonics. It may be
that a complex impedance load on the typical oscillator shifts its
operating conditions enough that even harmonics are generated, too,
but that's through a nonlinearity in the source, then. ANY
symmetrical waveform (that is, one in which the second half-cycle is
exactly the amplitude inverse of the first half-cycle) will have no
even harmonics.

The single impulse per cycle is very nice because the amplitude of all
the harmonics is nearly the same (out to where the pulse width of the
practical approximation to an impulse, that is a short pulse, starts
to become a significant fraction of a cycle of that harmonic).

Cheers,
Tom

> Hello--

The GE-X1 was part of GE's "low cost" experimenter line of
semiconductors.
Chances are, you could substitute any similarly-packaged SCR with
a rating of 500V PIV or more and it would work acceptably. Power rating
generally
correllates with package dimensions.

Ditto the 504A rectifier-- a 1N4007 (1 ampere) or 1N5408 (3 ampere)
diode (both
rated for 1000V PIV) should work acceptably unless the 504A was a
fast-recovery
type. To discern whether it's fast recovery, check the circuit to see
whether it's
rectifying 60 or 120 Hz, or whether it's used in a switched-mode power
supply.

Source record: 60310

It's pretty simple.

A 50/50 duty cycle square wave has no even harmonics. If the duty cycle is off from 50/50 even a tiny little bit then you start to get even harmonics. At a couple of percent (say 48/52 duty cycle) you have a second harmonic that's about 40 or 50 db below the fundamental component.

Logic gates and calibrator circuits are not infinite bandwidth devices so you will not get an infinite number of harmonics. They will only put out energy up to a certain point and that's it. The bandwidth limitation is what gives you a finite rise and fall time on the square wave out of a logic gate.

If the magnetrons still work I would be VERY carefully experimenting
with them. Two basic safety problems:

1) You have pretty high voltages present. Normal high voltage safety
measures should be used.

2) Those magnetrons put out a LOT of power. Even if it bounces off
three or four things before it hits you there's still more than enough
there to blind you or worse, much worse...

I would strongly recommend some of the little 10GHz gunplexer type
units as stuff to experiment with rather than microwave oven
magnetrons. They put out a lot less power and do neater things.
Generally you can find a couple for $40 or less ....

Just an opinion ....

There was an artical in 73 Magazine a few years ago if you can find it.
It tells how to set up and use the microwave parts for a transmitter.

Myron A Calhoun wrote:

Without spending ridiculous price for electroret condenser type mic for Icom rig, I would rather use studio type mic with compensation amplifier with bells and whistles (tone controls and compressions - if possible).

I have look through ARRL Handbook, but nothing useful can be found.

Is anybody out there can shed some lights on this ?

Many thanks in advance.

I'm thinking of building a miniature QRP (3-5W) tube-based transmitter, using a 7551 in the final, at reduced voltage. Is there any reason I can't use a broadband (ferrite core) impedance transformation to 50 ohms, and follow that with a fixed 50-ohm-to-50-ohm low-pass PI filter (like is done in solid state finals)?

I'm sure you're right, Bob. Is it periodic duty cycle, or symmetry
about "ground" that generates even harmonics?

Can anybody out there offer the mathematics that supports this?

The only real practical limit to your idea is that with a simple
transformer type arrangement, the capacitance of the plate winding
is usually equivalent to just about a short circuit to ground. probably
100 ohms or less. That kills the hell out of a 3k ohm desired imp.

It works ok with transistors where the collector imp can be as low as
a tenth of an ohm or so.

4164. INVITATION TO 3 ANTENNA REFLECTORS(LISTS)

>

Be a little careful while disassembling the ovens. I seem to recall an
article a while back that said that some microwave ovens used insulators
made from Beryllium Oxide. While BeO isn't hazardous in solid form,
if you attempt to machine it, you end up with powdered BeO, which is
very nasty in terms of health affects. Unfortunately, I don't remember
all of the details, but it might be worth doing some research.

>incandescent lamp?
>

Well, all you have to do is to solve Maxwell's equations to
determine how the fields exit the tube. Unfortunately, this could
be very difficult.

You might be able to approximate the exit as a slot antenna. Or,
you might be able to approximate it as a terminated waveguide. My
guess (and, it's only a guess) is that the waves probably exit and

form several lobes, although predicting the direction and intensity
of the lobes would be difficult without some emprical measurements.

>Lest anyone be concerned, I'm not particularly worried about the safty
>aspects--I (think I) have enounh brains to be elsewhere than the near
>vicinity of the tube if/when I try it, but none of the "fields and waves"
>courses I took (oh, so long ago) in college actually included any
>practical aspects of generating microwaves in them, and I'd like to try.
>

I'm EXTREMELY worried about the safety aspects! Most microwave ovens
produce microwave power in the 1KW range. This is an EXTREME amount of
power at microwave frequencies. Most hams that use microwaves generate
them via gunnplexers. A typical gunnplexer will produce about 10 milliwatts
of power, and you still see safety warnings about not looking into the
waveguide end of these things! With the microwave tube, you're talking
about five orders of magnitude more power! For example, if you had a
1KW laser, which can cut steel plate like a hot knife going through
warm butter, you wouldn't dream of looking into the beam. A 1KW microwave
source is about the same as the 1KW laser. Basically, what I'm trying to
say is please treat the tubes with lots of respect.

>Maybe I can make an anti-roach gun to operate in my garage overnight,
>or, if the waves will be pointable, maybe I can make an anti-mouse gun
>and leave it pointed at a mousehole in my barn. (I've caught seven mice
>in an outbuilding in the last three nights, so I should have plenty of
>"experimental subjects"!)
>

I'm not sure I'd want to do this; at least, not while living in the same
state! Consider where those microwaves may go. What might they reflect
off of? Where will they end up? What if someone walks
into the garage without realizing what's going on? Exploding
eyeballs are no fun!

Plus, you're running a bit of a risk that the animal rights activists
may get upset for irradiating mice or roaches.

>I'll probably trot one of the tubs up to the local university and see if
>any of the professors up there have any idea, but I'm also open to
>suggestions from y'all.
>

What frequency do the tubes operate on? Are they near an amateur band?
Magnetrons typically can't have their frequency pulled too much, and
they're probably not tuned for an amateur band. But, just think what
a great moonbounce system you could set up if they could be. Or,
radar. What license would you need for the frequency involved? Are
there any interesting chemical or material science experiments they
could be used in?

Hi Folks,

Just a short note to thank all of you who replied with so many practical
helpful suggestions and test methods to pin point causes
of motorboating.

Looks like I have several remedies to reduce motorboating
including but no limited to:
Make better layout, improved ps and mic bias decoupling, run headphones
in series to decrease peak currents, and use fresh good quality 9v
batteries and more as I study mailnotes.

THANK YOU for help and 73 from W6MIK.

Have a look for Jerry Sevick's "Transmission Line Transformers" book (http://www.noblepub.com/Nobleweb/Nobledetail.html#NP9) for lots of practical info on how broadband you can expect to make a transformer with fairly high ratio. I'm just guessing, but let's say you need a 4050 ohm plate load for the 7551; then to get to 50 ohms, you need a 9:1 turns ratio. That's fairly high! As the turns ratio goes up, the practical bandwidth goes down. You'll probably need to resonate the plate capacitance. You might be able to cover all of any one HF band without retuning, but I suspect you'll have trouble getting to even an octave bandwidth. See Sevick's book for details; as you read it, be sure to consider the actual value of plate load resistance you need to achieve and what therefore the optimum impedance for the line you wind on the core. 450 ohms? Ouch.

Cheers,
Tom

It's the duty cycle that determines the harmonic content. Easy way to
see this: if I subtracted just the right DC voltage from a signal
that wasn't symmetrical about ground, I'd have a signal that IS
symmetrical about ground. So the ground-symmetry part is simply the
DC value. Since the subtraction is a linear process, it doesn't
change the harmonic content at all.

Cheers,
Tom

Dean,

Today there is no need to use 60 Hz magnetics in HV power supplies.
Much less expense and weight and much better regulation when you run a
100 KHz switcher. Why the manufacturers of amateur HF amps are still
using 60Hz heavy transformers, I don't know. Must be cheaper for them?
For example, see article in Feb 1991 QEX on a 2KW switcher.

Linux does have an RF bandpass filter design program based
on double-tuned circuits.

For the digital stuff I cobbled together a simple window-method
program for low/high/bandpass filters, implementing the
equations more-or-less verbatim from Ifeachor and Jervis. I
also have a quick and dirty C translation of a FORTRAN imple-
mentation of the Parks-McClellan algorithm for the fancy stuff
(it does Hilbert Transforms, differentiators, etc.). Ugly, but
it works. No, I don't remember where I got it.

Your RF generator probably has a 50 ohm DC current path
right between its output terminals, one of which is
grounded. That's a little like trying to conduct a choir
with a chain saw. Most crystal oscillators are delicate,
high-impedance affairs - you must treat them gently. Try
coupling through a pair of small capacitors.

The Frederick Amateur Radio Club (FARC) presents the annual
Father's Day Hamfest on Sunday, June 18, 2000
from 8:00am to 3:00pm, rain or shine.
(Access for tailgaters opens at 6:00am)

It's at the Frederick County Fairgrounds on East Patrick Street in
historic Frederick, Maryland. Easy access from I-70 and I-270,
plenty of parking.

Talk-in on the 147.060(+) MADRA repeater.

We'll have Radios, Electronics, Computers, Acres of Tailgating,
Indoor Commercial Vendors, VE Testing and more.

Good food and refreshments available.

On the web go to http://www.qsl.net/k3erm/ for more info and a map.

General admission is a $5.00 donation.
Tailgating spaces are $5.00 each + general admission
Indoor tables are $10.00 each before June 10th, $15.00 after.

One of the largest and most popular hamfests in the
Baltimore/Washington metro area. Don't miss it!

Questions? E-mail k3erm@qsl.net

Thanks & 73,
Bob K9CMR

Myron:

Firing up a magnetron won't produce any interesting effects, and could produce some dangerous ones. Considering the risk to reward ratio, I wouldn't try it.

Most of the microwave ovens I've disassembled have a tube with a ceramic and metal probe about 3/4 of an inch long sticking out the bottom which fits down inside a sheet metal piece of waveguide when the tube is screwed to it. That is the radiating part of the tube. I have several here, waiting for the one in my oven to burn out.

I have also salvaged microwave ovens for the HV diodes and even used a fan from one to replace a 40 year old fan in a Johnson Thunderbolt. The plastic blade really moves a lot of air and is much quieter than the original.

The power transformers can also be used. Lots of good stuff in defunct microwave ovens.

4178. FS: Old Radio/Electron Tube Books (5): 1929 - 1957

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-27 00:00:00 UTC
From: oldbooks78@aol.com
Message-ID: <20000526212622.14508.00000300@ng-fa1.aol.com>
Source record: 60333

I currently have for sale the following old radio/electron tube books. Prices include book rate postage (within the US). The books are:

"Elements of Radio Communication" by John Morecroft, published in 1929 by John Wiley and Sons. The 269 page hardbound book is in good condition. There are pencil marks and notes on many pages, as well as notes inside the front and rear covers, but everything is readable and secure. Nicely illustrated throughout, with several photos of old vintage equipment. There is also a small pad of unknown purpose stapled to the first blank end paper. Available for $14.

"Practical Radio Communication; Principles - Systems - Equipment - Operation Including Short-wave and Ultra-short-wave Radio" by Arthur Nilson and J.L. Hornug, published in 1935 by McGraw-Hill. The 758 page book has blue cloth over flexible board covers. In good+ condition. There are some passages underlined in pen in the first 10 pages of the book, otherwise very clean. Nicely illustrated throughout. Available for $15.

"Communication Engineering" by William Littell Everitt, published in 1937 by McGraw-Hill. The 727 page hardbound book is in about fine condition. There is a previous owners name inside the front cover, and a few minor pencil notes on the first blank end page, otherwise very clean. Dark green cloth covers with gold lettering on the spine in particularly nice condition. Available for $13.

"Electronic and Radio Enginering" by Frederick E. Terman, published in 1955. The thick, 1078 page hardbound book is in about very good condition. The pages are generally clean, with no page tears, but with underlines on a few pages, and a previous owners name inside the front cover that is marked out with black marker. Black cloth covers in nice condition, with a strong binding. Lots of good info in this text. Available for $13.

"CBS Electron Tubes and Semiconductors Technician's handbook" first edition, first printing, published in 1957 by CBS-HYTRON. Unnumbered pages, about an inch thick, card covers with a spiral binding. The book covers receiving tubes, picture tubes, crystal diode reference guide, germanium and silicon diodes, silicon power rectifiers, transistors, special purpose tubes, tube type numbering system, use of tube testers, and much more. In very good condition. Available for $15.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks, and best regards.

Dave

A couple of things that can go wrong when feeding a VFO into a crystal socket:

1) Neither side of the crystal may be at ground. You may have to get a ground connection another way.

2) There is only a 50/50 chance the pin you pick first is the right one to drive.

3) The crystal pins may be D.C. hot. Grounding one or both may stop the whole thing from working at all. Best to DC block the signal going in.

Hope this helps.

Probably a combination of cost, EMC (the QEX design was notable for its complete lack of EMC precautions!) and reliability - the traditional transformer supply has much less to go wrong.

That only leaves weight... and I'm tempted to say that you 60Hz types don't know what a real heavy transformer is :-)

Just picked up a Midland 70-924B UHF Repeater to be configured as a digipeater hooked up to a Kantronics KPC9612 Plus
It has a 15 pin accessory connector on the back which I would assume is for a tone panel or other devices. Does anyone have any specs or hookup diagrams for this unit? It would be greatly appreciated.

Thanks to everyone.

Jay.

The tuned circuits have to resonate at 27 MHz. This has nothing to do with AM or FM. That's the type of modulation is used (amplitude modulation = AM; frequency modulation = FM). Those cheap little FM circuits have both types of modulation in them, more of FM though. You'll have build a whole new circuit to go to 27MHz AM.

> circiut?I never understood what would make a transmitter resonate on FM
> as opposed to AM and vice-versa.Thanks for any info.

There are two things involved in your question. Changing frequency to 27 mHz and changing the method of modulation to AM.

I don't know what the FM transmitter you are starting with uses for frequency control. If it is free running with a coil and capacitor for frequency setting, then, yes, you need new capacitor/coil combination to resonante on 27 mhz. However, as a free running oscillator, it may not stay where you want it.

If the FM transmitter uses crystal control, then you need to change crystals to set the frequency you want.

These changes are only going to affect the frequency of operation. You will need to make other coil and/or capacitor changes for the driver and output stages, filters, and possibly others as well to make sure you get RF out on the frequency you want.

Frequency Modulation (FM) means that information is carried by varying the frequency of the signal. The FM modulation is usually applied to the oscillator section of a transmitter to vary the frequency.

Amplitude Modulation (AM) means that information is carried by varying the amplitude (strength) of the signal. AM modulation is usually applied to the final amplifier stage.

You will need to build an AM modulator and disable the FM modulator.

I use 2 inch fiberglass pipe for masts, it comes in lengths of 30 and 40 foot each. You can also get it in different sizes too, my dad used a 6 inch diameter 44 foot tall piece with rotor at top and NO guy wires. It was stuck 4 foot in the dirt, and bracketed off at the 10 foot level to the side of the house, but that was it, and it stood up to high winds, we lived in tornado alley on TX/OK border....I have currently one 40 foot 2 inch mast up, it has been up for 4 years now, with two guy wires, and bracketed at 15 foot.

<clifto@clifto.com> wrote:

>How does an analog delay line work?

The electric signal is converted to sound and transmitted through a
suitable crystal and picked up by an other transducer at the other
end. The speed of sound is much less han the electric signal speed.
This is at least how the PAL delay line works, which delays the
chrominance signal by a full line period (64 us) to be summed after
inverting with the current chroma signal (which has also been inverted
since last line) to cancel any phase errors, which otherwise would
cause hue errors.

In very old computers, acoustic delay lines filled with mercury was
used as the main memory.

>For example, the massive old air-core
>coil found in older vintage color TVs, used to delay luminance for a bit
>to allow for all the extra chrominance processing?

I guess you are referring to the less than 1 us delay in the wider
luminance channel to compensate for the propagation delay in the
narrower chroma channel. As far as I know, this is some kind of
special coaxial cable with low velocity factor.

Hi Larry:

I live in Newberg and would love the HT-32b. Please let me know. My telephone number if 538-4301 or you can e-mail me.

I can pick it up at your convenience.

Thanks, Colin Lamb

Hi Larry:

I just wrote you.

Would be willing to pay you some money for the transmitter as it matches my Hallicrafters receiver. I sold my last HT-32b after learning I had cancer - but the cancer went away and I was without my rig.

Thanks, Colin

Its a transmission line for the signal. I made one by winding a coil
on a dowel that had a layer of metal foil (insulated where it lapped
over).

The coil and distributed capacitance makes a transmission line that has
some delay. The amount of delay depends on the inductance and
capacitance.
Also the characteristic impedance depends on those same two values.

or.....if you can get your "bug" to transmit on 27mhz, you ought to be able to slope tune it with your AM receiver as-is. Not even sure why you'd want to go (presumably) down to 27 Mhz for a bug though....most likely if the current freq is high then whatever it needs for an antenna will be MUCH more compact/efficient where it is......use a cheapo scanner to receive it. Best of luck though - tinkerin' is the GOOD stuff!

Source record: 60360

I need some info on using a Realistic pro-2025 16 channel scanner to activate a relay when the squelch is opened..... I want to use the scanner as a receiver on a remote base to key my 6 meter ham radio when the scanner receives a signal on the 440 mhz ham radio band.....Can anyone give me some information on this? I have been unable to find a schematic on the 2025 and I have been told that when the squelch opens there will be voltage come up on a pin inside the scanner..... Any ideas of how I might find that pin when I do not have a schematic? I am also open for any other advice on this subject.....

Thank you,
Dan (N4YSV)

Radio Shack is pretty good about having service manuals available for
their equipment, and I gather you can get them from even old equipment.
You'd have to order it, and I'm not certain of the specifics. Radio Shack
does have a website, it might be www.radioshack.com and that may have
the details about ordering.

With or without a schematic, if you're lucky the unit will use a standard
IC in the IF strip. Once you track down the data sheet for the device,
if the squelch is part of that IC, using it will be well defined.

Open the case, and look for a 14pin or more IC (assuming the receiver
isn't 25 years old). Chances are good that there will be a 455KHz ceramic
filter, a plastic block or thin rectangle usually marked with 455 and
the ones I've seen are orange or green and stand out, really close and
connected to some of the pins.

Get the number off the IC, and start looking in data books for a match.

If the data sheet shows a pin related to squelch, you're in luck. And
the data sheet should have a sample circuit schematic showing how things
are connected to it.

Of course, considering the type of receiver usually available for 27MHz,
I don't think slope detection will work.

Since the "bug" is undoubtedly not crystal controlled, and intended for
use with an FM broadcast receiver (ie wide deviation), when you try
listening to it on a narrow receiver like you'd find at 27MHz, you may
get nothing but a horrible mess. The narrow selectivity will only allow
the reception of a small portion of the carrier's deviation, and I don't
think that allows for proper demodulation. (The reverse, tuning a
narrow deviation signal on a wide deviation receiver, will give low
recovered audio because the deviation is only a small portion of the
slope, but at least the receiver is getting the full swing of the
transmitted signal).

Never mind that an LC oscillator at 27MHz will not be particularly
stable unless extreme care is put into it's design and construction.
An LC oscillator works in the FM broadcast band because the receivers
are wideband, so drift goes unnoticed.

Of course, this brings up the point that apart from other legalities,
an LC oscillator with wide deviation FM is not appropriate at 27MHz
where crystal control is expected and narrow signals are the norm.

From: Kenneth Scharf <kjre@flashcom.net>
Message-ID: <3931CA8D.D7ECDCB1@flashcom.net>
Source record: 60368

I am looking for an old IF transformer. The part I need would be in a 1 3/16 sq. can and have two compression trimmers on top. The unit would be a 455Khz First IF transformer, with an 'iron' core. An IF transformer pulled from an old "all american 5" radio would be fine, providing the coils were not open.

Please e-mail at: scharkalvin@yahoo.com or kjre@flashcom.net if you have such an item for sale or swap.

Thanks!

Kenneth Scharf WA2MZE

Me and a roommate play paintball often and figured it would be fun to make some headsets with low-power FM transceivers. I've located numerous low-power FM transmitters but haven't found any small receivers. Could anyone point me to some circuit schematics for any good FM receivers and transmitters? I'd greatly appreciate it!

If anyone has any resources on motion detectors, I'd apreciate that too (for night paintball :)

The older VTVM's used a divider network that totaled 10 Meg ohms, and so do the DVM's that I've worked on. The range was selected by picking a tap, not switching out resistors, so the load to the ground lead was a constant 10 Meg ohms. Also, if you have a meter with a 20 Meg ohm input impedance, parallel another 20 Meg ohms and you won't need to scale your readings. Above all, make sure the ground lead is in good condition, and never use a weak alligator clip. If the ground comes off, you can really get hurt, or killed.

4219. Ham Radio Design Freeware

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-05-29 00:00:00 UTC
From: Charles Reichert <kd9jq@rsg.org>
Message-ID: <393288D1.9F7497D3@rsg.org>
Source record: 60374

The following are Ham Radio Design Programs (DOS) that I'm
providing Free on my Web Site at;

http://www.mbn.net/kd9jq/hamradio/

ASP 4.0 - Amplifier Simulation Program for designing
FET and Bipolar Preamps, RF, IF Stages. Plots Gain,
Output VWSR, and NF while providing design parameters.
Other features also. Documentation.

TAP 2.0 - Triode Amplifier Program for designing High Power
Triode Grounded Grid Amplifiers. Provides Input, Output
Matching useable up through 2 Meters and design parameter's
beyond that. Calculates Bias voltage for specified Class
or Conduction Angle. Design Parameters, Documentation.

PLL2 and PLL3 for 2nd and 3rd Order Phase Locked Loop
Design. User inputs parameters and and design parameters
are calculated. BODE plots of Loop Response, Transient
provided. Documentation.

Misc Utilities - Utility programs for *BroadBand matching,
*Transistor Compression Pt., LP, *HP Filter design, and
PI or T Attenuator. The first 3 programs I added a GUI and
some programming corrections from code obtained from
RF Design Magazine a number of years ago.

The CATCH.....None. Just my way of giving back to the hobby.

The Ten-Tec 20m ==> 6m transverter is easily
modifiable to 10M => 6m. I've done it. The
Ten-Tec kit costs $95.00. You need one
(or 2) xtals for 50-52 or 52-54. I used 2
with diode switching. You need to change
a few parts. The LO in the Ten-Tec kit is
set for 36Mhz you change it to 22 and 24
(your 10M signal is 28 or 29 MHZ;
22+28 = 50, 22+29 = 51, 24+28 = 52,
24+29 = 53) The parts you change, other
than the xtal are to set the frequency
of the L/C circuits in the LO. If you
decide to build it, contact me and I'll
give you the values I used. Ed

John,

When lightning killed my ICOM 745 microphone, I replaced
the electret element with one from Radio Shack. Works
great and only cost a few bucks. You could brew one from
an old CB mike replacing the element, or build a desk mike
without spending a lot. The connector will cost you more than
the element.

The lightning strike was interesting. I heard thunder and ran
to the shack to disconnect stuff. Got there in time to watch an
arc jump out of the old style ma bell telephone sitting on the
desk near the mike. The arc went from the base of the phone
into the mike. The phone (instrument) was unaffected but
we lost phone service for over a day and cable TV for a few
days. A solid state wall phone was toast. (No visible damage)

I need the following parts for my Racal RA6790/GM.

1) LCD, (Function Display) Part# 08526

2) ISB Option

3) Top and bottom covers.

Will also consider a Junker Unit. I also need a source for the 2.4 dc
Ni-Cad Battery.

Here is a list of the large size filters that Heath used:
Part no. Type Bandpass, 6 dB--60dB Used on
404-200 SSB 2.1 kHz 5 kHz 100/300/400
404-201 AM 3.5 kHz 14 kHz same
404-202 CW 400 Hz 2.5 kHz same

Here is a list of the small size filters that Heath used:
Part no. Model no. Type Bandpass6/60 Used on
404-283 SBA-310-2 SSB 2.1 kHz/5 kHz 300/400
404-284-1 SBA-301-2 CW 400 Hz/2 kHz same
404-285-1 SBA-301-1 AM 3.75 kHz/10 kHz same
404-314 -------- AM 5 kHz/15 kHz 310/313
404-328 SBA-310-1 SSB 2.1 kHz/7 kHz 100/101/310

404-548 -------- CW 400 Hz/2 kHz 104/104A only

I just picked up an MFJ-1786 Magnetic Loop Antenna. It had
a few problems and had been tampered with. I have restored
it to original condition and am just waiting for decent
weather to put it outside. I have a few questions and would
like to talk to anyone who has spent time with one of these
antennas. Thanks in advance for any replies.

WELL!

I thought my comments might stir something up, HI.

Lessee, how many pounds would a shield cover and a good lowpass line
EMI filter weigh (and cost) for, say, starting at the 10th harmonic of
100 KHz? Methinks a lot less than one each 60Hz 2KVA transformer.
We are living with 250+ watt switchers now in our PC's, made dirt
cheap in high volumes, including EMI filtering to meet FCC Class B.
On the other hand, I have heard of Icom's switcher that made it to
market, and generated gaboons of RFI.

From: JW <jdwalton@home.com>
Message-ID: <393455EA.A4DC87E@home.com>
Source record: 60249

I am building a device with multiple (i.e. over 100, perhaps 180) T 1 3/4 LED's - red, blue and green ultrabrites and using PWM to control the intensity. Reading through Agilent's ap-notes I see that LED's in parallel is not recommended (i.e. each LED is recommended to have its own series resistor). How strictly should this discipline be followed - i.e. not paralleling any?

Weight is no contest - the switcher wins, every time.

Cost and reliability are much less certain.

> We are living with 250+ watt switchers now in our PC's, made dirt
>cheap in high volumes, including EMI filtering to meet FCC Class B.

But unfortunately we are *not* yet living in an era of 2.5kW+ switchers that are easy to custom design and dirt cheap to make in small volumes - and we may never be. Large, high-voltage switch-mode supplies are highly specialized items to design, and suitable transformer cores in particular are difficult to source in small quantities.

> On the other hand, I have heard of Icom's switcher that made it to
>market, and generated gaboons of RFI.
>
Since the Icom switcher must have passed the regulatory tests, it shows that the standards themselves aren't good enough to protect users of weak signals from interference... but we probably could have guessed that.

Reg: Most of the Heathkits used a 3395 KHz IF. Some of the '70's Kenwoods used that frequency also. Yaesu used a 31-something IF about the same time. Most filters were 6-pole for SSB and 4-pole for CW. INRAD I believe lists replacement filters and attendant specs for lots of radios. For really good, really high priced filters, Network Sciences is hard to beat.

Try this. Connect the signal generator to the xtal socket
with a 1/4 wave long coax cable. Remember to take into account the
velocity factor or the coax. This creates a low Z to high Z matching
transformer. Don't let the long length bother you. It works.

I got a VOX headset for an Alinco HT and I want to wire it to my FT-847 PTT.. What I need to know is how to make this thing close the circuit on the PTT connection on the 847...I am sure I must get power to the VOX unit somehow.... The plug on it (for the mic) has three wires.... One goes to the tip, 1 goes to the center ring and the other goes to the shaft....Where does it get its power from? Does the alinco HTs have power on either the ring or the tip of the mic plug??? I have been told that this VOX also works on some icom HTs.... Can anyone give me some advice?

Thanks,
Dan (N4YSV)

4239. Re: Mic Amp

Newsgroup: rec.radio.amateur.homebrew

Source record: 60386

I use the Radio Shack electret mic element for my station mic.
I fed it with a well regulated and filtered +8 volts from a
78L08, and into a standard mic preamp made from a NE5532 Op
Amp. The first section of the Op amp is configured as a non-
inverting amp with gain variable from 1 to 20 dB. The second
section I use to drive a solid state VU meter. I like to know
where my audio is without relying on the ALC metering on my rig
to tell me.
If you don't want the bells and whistles, simply run the
voltage source to the mic through a 4.7K resistor. Place a
capacitor between this assembly and your rig's audio input. This
will provide relatively decent mic audio for your rig.

Hello!

What's the design? Hollow- or solid-state? How many do you need, and
what about other parts?

I have some of the SB/HW 100/101 SSB filters, and also a set of
heterodyne crystals. Plus lots of info on how they work. Always looking
for ideas, too.

CF is roughly 3395 kHz. Z in/out 2000 ohms, resistive.

The CW filters show up on ebay at times, and prices vary all over the
place.

This is done mainly because each led has a very slightly differant
voltage drop, and when you put them in parallel they will have
a drastically differant brightness. One will always be brighter than
the other if you have two in parallel. So the resistors become
'equalizers' by nature.

I have one, and i love it. seems to work well. One word of caution,
it has such an extremely high Q that it is hard to get the SWR balanced,
and the bandwidth is so narrow, you must re-tune if you move even a few
KHZ. When you are 'dialed in' exactly right, it is hard to beat this
little 'apartment dweller sized' antenna!!!

I am looking for plans to make a small mini RS232 terminal.

The idea is to make a packet cluster terminal for RX only. I need to input the RS232 data from a TNC's output direct to an LCD display interface, rather than into the serial port of my PC.

Any Ideas how this can be done?
PIC16F84 etc....

If you don't want to get into assembler programming try the BasicStamp II from Parallax or the BX24 from Netmedia. There are newsgroups for both, they program rather easily right off the serial port of a pc and there are easy programs to use serial LCD displays, or to take serial, Dallas One Wire, etc input.

The BX24 was recently reviewed in Circuit Cellar.

> small. Any help would be appreciated.

Hello--

Believe it or not, you can build an FM receiver with only one active device: the circuit
is called a "superregenerative detector". The active device (tube or transistor)
oscillates at two frequencies: the signal frequency (e.g., 88 to 108 MHz) and a lower
frequency called the "quench" frequency. Generally, the quench frequency is twice
the highest modulation component in the signal frequency (say, 40 to 100 KHz for FM
broadcast reception).

You can build the circuit with one active device (called a self-quenched detector) or
two (one device oscillates at the signal freqnency and the other at the quench frequency.

The quench frequency modulates the signal-frequency oscillations, suppressing
signal-frequency oscillations in one state and allowing the oscillator to fully oscillate another, second state. In between the two states, the signal-frequency
oscillator balances on the verge of oscillation, and incoming signals (or random
noise) pushes the circuit into oscillation.

Thus, the superregen is capable of large amounts of gain, but the signal-freqency
oscillation gets reradiated from the detector, making the circuit unpopular with
onther sensitive receivers using that portion of the radio spectrum. You can
add an RF amplifier stage, but then you're up to two or three active devices.

For more information, do a web search for the topic; also, look for
"fremodyne",
another 1940s variant. Also, look in older editions (say, pre-1970) of the
ARRL's
"Radio Amateur's Handbook".

BTW, go ahead and build a superregen-- it's an amazing little circuit.

Those old TRS-80 model 100 laptops make a great terminal. They have a terminal program in ROM. I have seen them for $10 at flea markets. PIC16F84's will set you back $5.

Of course, if you just want to build one anyway, for the learning aspect of it, go for it. The BASIC Stamp is a good starting point, as another writer has already stated.

Good luck,
Allan Dobler

> i.e. not paralleling any?

Well, it works like this, suppose you have a single LED rated for 20 ma and you use a 5v power supply, then you need a 250 ohm resister in series with the LED to ensure that you receives no more that 20 ma. This gives you 0.1 watts of power. Now if you parallel 2 resisters together the total current available is still 20 ma but if both are on then you only get 10 ma into each giving you 0.05 watts of power each. The LEDs will therefor not be as bright. however if only one is on at a given time then it will be as bright as the LED that has it's own resister and is not paralleled with any other LED.

I think you can see the problem here. You want to vary the intensity of the LEDs using PWM but unless you can take into consideration how many LEDs will be on or off in a given parallel circuit you cannot accurately determine the needed PWM period since the intensity is a function of available current.

Large, high-voltage switch-mode supplies are highly
> specialized items to design, and suitable transformer cores in
> particular are difficult to source in small quantities.
>
Ian OM,

Switchmode power supplies are "highly specialized" no more than any other current technology that is at least several years old. At least a couple of suitable ham radio designs have been published in the last ten years or so. A 2KW power supply Ferrite toroidal core, for example (use two at 100KHz) can be purchased in unit quantities from Amidon for under $12 each (FT-193A-F). There is nothing magical about switching power supplies. And very few hams need to custom design anything. I don't. If at all possible, I copy proven designs, and make departures from them that I am comfortable with (usually to save $$). Same as building a GaasFet preamp for 70cm, or a circuit with SMT components, a QRP rig, or anything else "new" to the constructor.

I do agree with you about FCC B certification. It does not match the needs of nearby weak-signal receivers (nor was it intended to); particularly if the receiving antenna is located close to the rig. But with antennas up in the air a ways and well away from the rig (where they belong), and using properly shielded or balanced feedlines, high-order harmonics from even non-FCC B compliant 250W supplies are inaudible, particularly on the higher HF bands, in my experience. Further, keep in mind that even if the switching supply were noisy, it can be shut down in milliseconds and disabled while receiving. This can be a very acceptable solution for many of us. So, there are ways...

All I am getting at is let's not put certain things in the "magical, impossible to do" category, just because they are not yet commonplace in homebrew or commercially manufactured ham radio equipment. The manufacturers' criterion is more complex than just technological, and includes marketing tradeoffs that can (very often, unfortunately) override technical ones.

In 12VDC setups I've run multiple LEDs in series -- picking the
proper resistor to limit the current.
However, you might not want to do that for "...over 100, perhaps 180..."
If one fails in an 'open' (vs. a short) the whole thing goes dark.
And, you'd need to have a HV DC (albeit low current) suppy.

Hi Ed,

Have you looked at the spectral purity of the output? The reason T-T
chose 20M was because of the increased cost in filtering needed to keep
2X the LO (44-46 MHz) and 2X the IF (56 MHz) out of the output when
using a 10M IF. These freqs are very close in to Fout.

Dale W4OP
